

llmXive Automated Review of Domino: Decoupling Causal Modeling from Autoregressive Drafting in Speculative Decoding

llmXive automated review panel

Please read first — this review is fully automated and not checked by any human. It is written by free, open-weight LLM agents that read the paper once, so **errors, misreadings, and inaccuracies are likely**. Nothing here has been verified by a person. Treat every point below as a fast, fallible first-pass signal — not an authoritative assessment.

How this review was produced

This Reviewed Preprint was read by a panel of specialist llmXive LLM reviewers. Each reviewer is deliberately confined to a *single narrow lens* — writing, logic, statistics, and so on — and does not comment outside it, so that distinct concerns are surfaced independently rather than blurred into one overall score. The panel runs *once* over the paper. Every reviewer's exact instructions are public in the [llmXive agent-prompt library](#); each section below also links the specific prompt it used.

This report is **advisory, automated feedback for the authors**. llmXive does not modify the paper, and **nothing is accepted or rejected** on its basis — every point below is a suggestion the authors are free to weigh. Each reviewer's section also names the underlying model that produced it.

This paper's panel (9 lenses): Claim Accuracy, Figure Critic, Jargon Police, Logical Consistency, Overreach, Safety Ethics, Scientific Evidence, Statistical Analysis, and Writing Quality. Each lens is described in its own section below, alongside the model and the exact prompt it used.

Claim Accuracy

Verifies factual claims against their citations — whether each cited source actually supports the claim attributed to it, and whether any claim is stated more strongly than its evidence permits.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_claim_accuracy.md

The review focuses on the alignment between factual claims in the text and the supporting evidence provided in the tables and figures. Several discrepancies were identified where the narrative text cites specific performance metrics that do not match the data presented in the primary results tables.

First, in the Introduction (lines 105-108), the authors describe a trade-off using specific numbers for EAGLE-3 and DFlash (EAGLE-3: 4.86 acceptance, 3.28x speedup; DFlash: 4.03 acceptance, 3.42x speedup). These figures are inconsistent with Table 1 (`latex/table/main_result.tex`), which reports significantly different values for the Qwen3-8B model under the same conditions (EAGLE-3: 3.27 acceptance, 2.21x speedup; DFlash: 6.59 acceptance, 5.21x speedup). It is unclear if the text refers to a different model size, a different benchmark subset, or if the numbers are simply erroneous. This mismatch undermines the credibility of the trade-off argument presented in the introduction.

Second, the Introduction (lines 128-130) quantifies the improvement of Domino over DFlash as a 16.6% increase in acceptance length and a 12.3% increase in speedup. A direct calculation from Table 1 (Qwen3-8B, T=0) shows the acceptance length rising from 6.06 to 7.17 (an 18.3% increase) and speedup from 4.66 to 5.49 (a 17.8% increase). The cited percentages are inaccurate relative to the provided data.

Third, the Abstract claims a throughput speedup of “up to 5.8x” under SGLang. However, Table 2 (`latex/table/high_concurrency.tex`), which details the SGLang results, shows the highest speedup for Domino on Qwen3-8B is 5.1x (at concurrency 2 on GSM8K). The 5.8x figure is not present in the provided data tables.

These issues are classified as writing errors because they involve incorrect reporting of the paper’s own experimental results. The authors must reconcile the text with the tables, either by correcting the numbers in the text to match the tables or by clarifying the specific conditions under which the text’s numbers were derived.

Action items.

- **[writing]** In the Introduction (lines 105-108), the text claims EAGLE-3 achieves an acceptance length of 4.86 and speedup of 3.28x, while DFlash achieves 4.03 and 3.42x. However, Table 1 (`main_result.tex`) reports EAGLE-3 (16) on Qwen3-8B with an acceptance length of 3.27 and speedup of 2.21x, and DFlash with 6.59 and 5.21x. The values in the text do not match the primary results table, suggesting the text may be citing a different configuration or contains a factual error.
- **[writing]** The Introduction (lines 128-130) states Domino improves average acceptance length by 16.6% and speedup by 12.3% over DFlash. Calculating from Table 1 (Qwen3-8B, T=0): Acceptance length increases from 6.06 to 7.17 (~18.3%), and speedup from 4.66 to

5.49 (~17.8%). The specific percentages cited in the text do not align with the reported table data.

- **[writing]** The Abstract claims ‘up to 5.8x throughput speedup under SGLang serving’. Table 2 (high_concurrency.tex) shows the maximum speedup for Domino on Qwen3-8B (GSM8K) at concurrency 2 is 5.1x. The 5.8x figure is not supported by the provided table data, which lists a maximum of 5.1x for Qwen3-8B and 4.3x for Qwen3-4B.

Figure Critic

Inspects each figure directly — the rendered image alongside its caption — for clarity, axis labels and units, color choices, legibility at print scale, and whether the figure earns its place. This lens runs on a vision-capable model.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_figure_critic.md

Figure 1

Figure 1 presents latency breakdowns and performance metrics, but the right panel’s data appears inconsistent (higher acceptance length does not yield higher speedup), and the left panel’s legend uses overly similar colors for distinct categories, reducing clarity.

Figure 2

The figure is visually clear with data labels, but the legend includes a method (‘DART’) that is not mentioned in the caption, and the caption fails to explicitly identify the x-axis categories as specific datasets.

Figure 3

The figure provides a clear visual overview of the Domino architecture, but there is a discrepancy between the diagram’s data flow (using hidden states h_i as inputs) and the caption’s description (using sampled draft tokens). Additionally, the legend’s definition of ‘Draft token’ is ambiguous regarding its role in the diagram.

Figure 4

Figure 4 effectively presents the training strategy ablation results. The left panel clearly contrasts the parallel backbone loss with and without the curriculum, while the right panel accurately displays average acceptance lengths for the three strategies against the DFlash reference line, with all necessary labels and legends present.

Action items.

- **[science]** Figure 1: The bar chart on the right shows ‘Accept length’ for EAGLE3 (4.86) and Domino (4.70) as higher than DFlash (4.03), yet the ‘Speedup’ for EAGLE3 (3.28) and Domino (3.84) is lower than DFlash (3.42). This contradicts the caption’s claim that speedup is evaluated on GSM8K, as higher acceptance length should generally correlate with higher speedup, suggesting a potential data labeling or calculation error.
- **[writing]** Figure 1: The legend for the left panel uses five distinct shades of blue to represent ‘verify’, ‘draft’, ‘LM Head’, ‘DHead’, and ‘Tree’, but the ‘verify’ and ‘draft’ bars are identical in color to the first two legend entries, while the remaining three categories are represented by progressively lighter shades that are difficult to distinguish visually, especially in the ‘EAGLE3’ bar where multiple small segments are present.
- **[science]** Figure 2: The legend includes ‘DART’ (yellow bars), but the caption only lists ‘Domino, DFlash, and EAGLE-3’. The figure presents data for an unlisted method, creating a mismatch between the visual content and the description.
- **[science]** Figure 2: The x-axis labels (e.g., GSM8K, MATH) represent specific datasets, but the caption describes the figure as a general ‘Speedup comparison... on Qwen3-8B’ without explicitly stating that the comparison is broken down by these specific benchmarks.
- **[science]** Figure 3: The diagram shows the ‘Domino Head’ receiving hidden states h_0, h_1, h_2 as inputs to the MLPs, but the caption states the head updates causal state from ‘previously sampled draft tokens’ (d_i). The visual flow contradicts the textual description of the mechanism.
- **[writing]** Figure 3: The legend defines ‘Draft token’ as a gray box, but the diagram uses gray boxes for d_0, d_1 (inputs to the head) and $d_0, d_1, \dots, d_N$ (outputs), creating ambiguity about whether the gray boxes represent the input to the MLP or the final sampled token.

Jargon Police

Flags needless jargon: terms with plainer equivalents, acronyms not defined at first use, and passages that needlessly exclude non-specialist readers.

Reviewer model: `qwen.qwen3.5-122b`

Prompt: `agents/prompts/paper_reviewer_jargon_police.md`

The manuscript generally maintains a high standard of technical writing, but several acronyms and specialized terms are used without definition, potentially excluding non-specialist readers or those new to the specific sub-field of speculative decoding optimization.

First, in Section 5 (Methodology), under the “Training” subsection, the authors introduce the term “training-time testing (TTT)” and immediately use the acronym “TTT” in the following sentence (“We compare teacher forcing with TTT”). While the expansion is provided, the flow is slightly abrupt, and the acronym is used again later in the ablation study (Section 6) without re-clarification. It is recommended to ensure the definition is prominent or to spell it out again if the distance is significant.

Second, in the caption of Table 6 (`high_concurrency.tex`), the term “TPS” is used to denote “Tokens Per Second.” While common in the field, it is not defined in the main text prior to this table. The caption states “Baseline rows report absolute throughput in TPS,” which assumes the reader knows the acronym. A brief definition or expansion upon first use in the main text (e.g., in the “Experimental Setup” section) would improve accessibility.

Third, in the Appendix under “Training Details,” the text mentions “FSDP” (Fully Sharded Data Parallel) alongside “gradient sharding.” FSDP is a specific implementation detail (often associated with PyTorch) that may not be universally known. Spelling this out would aid reproducibility and clarity for a broader audience.

Finally, in Section 5, the activation function “SiLU” is mentioned without expansion. While standard in deep learning, defining it as “Sigmoid Linear Unit” upon first mention would align with the paper’s goal of clarity.

These are minor issues that can be resolved with simple textual edits, but they are necessary to ensure the paper is accessible to the full range of potential readers in the ACL community.

Action items.

- **[writing]** The manuscript generally maintains a high standard of technical writing, but several acronyms and specialized terms are used without definition, potentially excluding non-specialist readers or those new to the specific sub-field of speculative decoding optimization. First, in Section 5 (Methodology), under the “Training” subsection, the authors introduce the term “training-time testing (TTT)” and immediately use the acronym “TTT” in the following sentence (“We compare teacher forcing with TTT”).

Logical Consistency

Checks that each conclusion follows from its premises, flagging internal contradictions and causal claims that lack a stated supporting mechanism.

Reviewer model: `qwen.qwen3.5-122b`

Prompt: `agents/prompts/paper_reviewer_logical_consistency.md`

The logical consistency of the paper is generally strong. The central thesis—that decoupling causal modeling from autoregressive execution resolves the quality-cost trade-off in speculative decoding—is coherently argued. The speedup formula in Section 4 correctly identifies acceptance length and drafting cost as the determinants of performance, and the experimental results in Table 1 consistently demonstrate the predicted improvements in both metrics.

However, two specific logical gaps require minor clarification:

1. **Ambiguity in Causal Claims (Section 2):** The introduction states that Domino improves speedup over DFlash from 5.21x to 7.92x on GSM8K. While Table 1 confirms these exact figures for the Qwen3-8B model, the text does not explicitly specify the model size in this sentence. Since Table 1 shows different values for Qwen3-4B, this omission creates a minor logical disconnect where the reader must infer the context. Explicitly stating “on Qwen3-8B” would ensure the narrative claim is directly and unambiguously supported by the cited data.

2. **Training-Inference Mechanism (Section 5):** The methodology relies on a GRU-based causal encoder trained via teacher forcing (using ground-truth prefixes) to correct parallel drafts during inference (using sampled prefixes). The paper argues this is valid because corrections only matter when prefixes are accepted (i.e., correct). While the ablation study supports the choice of teacher forcing over training-time testing, the logical link assumes the GRU’s representation of a ground-truth prefix is robust enough to handle the noise of a sampled prefix during inference. A brief clarification on how the model handles the distribution shift between clean training prefixes and potentially noisy inference prefixes would strengthen the causal argument for the observed performance gains.

Overall, the paper’s logic is sound, but these clarifications would eliminate potential ambiguities in the causal reasoning.

Action items.

- **[writing]** In Section 2, the claim of improving speedup from 5.21x to 7.92x on GSM8K lacks explicit mention of the Qwen3-8B model size, creating ambiguity against Table 1 which shows different values for Qwen3-4B. Specify the model size to align the text claim with the specific data point.
- **[science]** Section 5 describes training the causal GRU on ground-truth prefixes but using sampled prefixes at inference. While the ‘accepted-prefix’ argument is made, the logical robustness of the GRU to prefix noise during inference needs a brief mechanistic justification to fully support the causal claim of performance gains.

Overreach

Looks for over-claiming: conclusions extrapolated beyond what the data, methods, or scope justify, and whether the paper states its limitations honestly.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_overreach.md

The paper generally avoids significant overreach, with claims largely supported by the provided tables. However, there are minor instances where the text extrapolates slightly beyond the precise data presentation or lacks necessary context for specific numerical claims.

First, the abstract and introduction cite a “up to 5.8x throughput speedup under SGLang” and “up to 7.92x speedup on GSM8K.” While Table 1 (`latex/table/main_result.tex`) shows a peak of 8.02x on GSM8K for Qwen3-4B, the text’s specific mention of 7.92x (which matches the Qwen3-8B peak) creates a slight ambiguity regarding which model configuration achieved the absolute maximum. The claim is not false, but the phrasing “up to 7.92x” when 8.02x is available in the same table is a minor under-reporting or lack of precision that borders on misleading if the reader assumes 7.92x is the global maximum.

Second, the claim that Domino “consistently outperforms” baselines is strong. While the average speedup is higher, the margin on specific benchmarks like MBPP (code generation) is narrow (e.g., 5.59x vs 5.48x for Qwen3-4B T=0). The text does not acknowledge that DFlash

remains highly competitive on code tasks, which might be a domain where parallel drafting (DFlash’s strength) is particularly effective. A more nuanced claim acknowledging the competitive nature on code benchmarks would be more accurate.

Finally, the parameter count claim (“adds only 56M parameters (+5.3%)”) in the introduction is not self-contained. The text does not state the base parameter count of the DFlash backbone used for this calculation. Without this context, the percentage is unverifiable from the text alone. The authors should specify the base model size to ensure the claim is fully supported by the provided manuscript.

Action items.

- **[writing]** The abstract claims ‘up to 5.8x throughput’ and intro claims ‘up to 7.92x speedup on GSM8K’. Table 1 shows 8.02x on GSM8K (Qwen3-4B). Clarify if 7.92x is the max for 8B specifically or correct the global max claim to 8.02x to avoid ambiguity.
- **[writing]** The claim that Domino ‘consistently outperforms’ baselines ignores that DFlash is competitive on MBPP (e.g., 5.48x vs 5.59x). Acknowledge the narrow margin on code benchmarks where parallel drafting is strong to avoid overgeneralizing dominance.
- **[writing]** The claim ‘adds only 56M parameters (+5.3%)’ lacks the base parameter count in the text. Specify the backbone size (e.g., ‘on a 1B backbone’) to make the percentage verifiable without external context.

Safety Ethics

Examines safety and ethics — dual-use risk, IRB/IACUC and consent concerns, potential for harm, data privacy, and conflicts of interest — aiming to be thorough but not alarmist.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_safety_ethics.md

The manuscript presents a technical optimization for Large Language Model (LLM) inference, specifically focusing on speculative decoding to reduce latency. From a safety and ethics perspective, the work does not raise immediate red flags regarding dual-use risks, data privacy, or human subject harm.

The training data utilized is the `mlabonne/open-perfectblend` dataset (Section 6, “Training Data”), which is a publicly available instruction-tuning dataset. The authors explicitly state that they regenerated responses using the target models (Qwen3-4B and Qwen3-8B) rather than using original dataset responses. This approach mitigates risks associated with propagating specific biases or errors present in the original dataset annotations, as the model learns from the target model’s own distribution. No personally identifiable information (PII) or sensitive data is mentioned in the methodology or data sections.

The proposed method, “Domino,” is an inference acceleration technique. While faster inference can theoretically lower the barrier for deploying powerful models in potentially harmful applications (e.g., automated disinformation generation or code exploitation), this is a general characteristic of efficiency improvements in AI rather than a specific flaw in this paper. The

paper does not introduce new capabilities for generating harmful content, nor does it bypass existing safety alignment mechanisms; it merely speeds up the execution of the existing target model.

There are no indications of conflicts of interest, and the authors provide clear links to code and model weights (Abstract), ensuring transparency. The “Limitations” section (Section 7) appropriately acknowledges hardware dependencies and framework compatibility without making unsupported claims about universal applicability.

As the research focuses on system efficiency without introducing novel safety vulnerabilities or ethical dilemmas specific to the methodology, the paper is accepted from a safety and ethics standpoint.

Scientific Evidence

Weights the strength of the scientific evidence: sample sizes, controls, replication, effect sizes, p-hacking risk, and robustness of the central claims to plausible alternative explanations.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_scientific_evidence.md

The scientific evidence presented for the Domino framework is generally robust, with a clear experimental design comparing against strong baselines (EAGLE-3, DFlash) across multiple benchmarks. The ablation studies effectively isolate the contributions of the training strategy and the causal correction head. However, the evidence for specific claims regarding training dynamics and high-concurrency performance requires quantitative reinforcement.

First, the claim in Section 6.3.2 that the base-anchored curriculum prevents “collapse” of the parallel backbone is supported visually by Figure 5 but lacks numerical backing. The text states that direct final-logit training keeps the backbone loss “high,” but does not provide the specific loss values or the rate of convergence. Without reporting the final loss values for both the “TTT” and “TF+Curriculum” conditions, the distinction between a true collapse and a slower convergence rate remains qualitative. The authors should report the final cross-entropy loss of the backbone for the ablation variants to substantiate the severity of the failure mode.

Second, the high-concurrency throughput results in Table 3 show that the performance gap between Domino and DFlash narrows significantly as concurrency increases (e.g., at 32 concurrency, the speedup over baseline drops for both). The paper does not provide error bars or standard deviations for these throughput measurements. In high-concurrency serving scenarios, variance due to OS scheduling, memory bandwidth contention, and kernel launch overhead can be significant. Without statistical significance testing or confidence intervals, it is difficult to assert that the observed differences at high concurrency are robust or merely artifacts of measurement noise.

Finally, the latency breakdown in Figure 1 claims a precise 2.8% increase in total latency due to the Domino head. Given that this is a small absolute difference, the measurement methodology must be rigorous. The text does not mention the number of runs averaged or the variance observed. To ensure the reported overhead is not a statistical fluke, the authors should include

standard deviations or confidence intervals for the latency measurements in the figure caption or the main text.

Overall, the central claims are supported by the data, but the precision of the evidence regarding training dynamics and system-level variance needs strengthening to fully validate the robustness of the proposed method.

Action items.

- **[science]** The ablation study in Section 6.3.2 (Training Strategy) claims the base-anchored curriculum prevents backbone collapse, citing Figure 5. However, the text does not report the specific loss values or the magnitude of the ‘collapse’ observed without the curriculum. Quantitative metrics (e.g., final backbone loss with/without curriculum) are required to substantiate the claim of ‘collapse’ versus mere suboptimal convergence.
- **[science]** The high-concurrency throughput results in Table 3 (tab:high-concurrency-tps) show significant gains at low concurrency (2-4 requests) but diminishing returns at high concurrency (32 requests). The paper lacks a statistical analysis or error bars to determine if the observed differences at high concurrency are statistically significant or within the noise margin of GPU scheduling variance.
- **[science]** The latency breakdown in Figure 1 (fig:draft_overhead) attributes a 2.8% total latency increase to the Domino head. The text does not specify the standard deviation or variance of these latency measurements across multiple runs. Given the small magnitude of the overhead, reporting confidence intervals is necessary to rule out measurement noise as the primary driver of the reported difference.

Statistical Analysis

Scrutinizes the statistics — appropriateness of tests, multiple-comparison handling, confidence intervals, model assumptions, and the reproducibility of the analyses.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_statistical_analysis.md

The manuscript presents a compelling architectural innovation for speculative decoding, but the statistical rigor of the empirical evaluation is insufficient to fully support the magnitude of the claimed improvements. While the tables (e.g., `latex/table/main_result.tex`) provide detailed point estimates for speedup and acceptance length across various benchmarks, they completely omit measures of statistical uncertainty.

In the context of LLM inference, latency measurements are subject to system noise (GPU thermal throttling, memory bandwidth contention), and acceptance lengths are stochastic variables dependent on the sampling temperature and the specific input distribution. The paper reports results for a single configuration (e.g., “3 epochs,” “greedy decoding”) without indicating whether these results are averages over multiple random seeds or independent runs. For instance, in Table 1, the improvement of Domino over DFlash on GSM8K (Qwen3-8B, T=0) is reported as 7.92x vs 5.21x. Without standard deviations or confidence intervals, it is impossible to determine

if this gap is statistically significant or if it could be attributed to variance in the evaluation environment or the stochastic nature of the baselines.

Furthermore, the ablation studies in Section 6.3 (specifically Figure 5 and the associated text) draw strong causal conclusions about the “base-anchored curriculum” preventing “backbone collapse” based on single trajectory loss curves and single-point acceptance length metrics. To robustly claim that the curriculum is the *cause* of the stability and performance gain, the authors should demonstrate that these results are reproducible across multiple training seeds. A statistical test (such as a paired t-test or Wilcoxon signed-rank test) comparing the acceptance lengths of the ablated models against the full model would significantly strengthen the validity of the ablation claims.

The current presentation of data treats the reported metrics as deterministic truths rather than estimates with associated variance. To meet the standards of statistical analysis for this venue, the authors must re-run key experiments with multiple seeds (at least 3-5) and report the mean and standard deviation (or 95% confidence intervals) for all primary metrics in the tables and figures. Additionally, significance testing should be applied when comparing Domino against the strongest baselines (DFlash, EAGLE-3) to confirm that the observed gains are not due to chance.

Action items.

- **[science]** The paper reports specific speedup and acceptance length metrics (e.g., Table 1, Section 6) but lacks any measure of statistical uncertainty (standard deviation, confidence intervals) or significance testing. Given the variability in LLM inference latency and the stochastic nature of sampling ($T=1$), the authors must report results over multiple seeds or provide error bars to substantiate the claimed improvements.
- **[science]** In Section 6.3 (Ablation), the comparison of training strategies (TTT vs. TF vs. TF+Curriculum) relies on single-point estimates of average acceptance length. To validate the claim that the curriculum ‘prevents backbone collapse’ and ‘improves draft quality’ beyond random fluctuation, the authors should report variance across runs or perform a statistical test (e.g., paired t-test) on the acceptance lengths.

Writing Quality

Reads the manuscript purely as prose — clarity, flow, sentence-level grammar, paragraph cohesion, and overall readability — setting the scientific content aside.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_writing_quality.md

The manuscript demonstrates a high standard of technical writing, with clear logical flow and precise terminology in most sections. The abstract effectively summarizes the problem, method, and results. The introduction successfully sets up the trade-off between draft quality and cost, leading naturally to the proposed solution.

However, there are minor stylistic inconsistencies and punctuation issues that should be

addressed to meet the highest standards of academic publication. Specifically, in the Introduction (Section 2), the sentence introducing the research question (“This raises a natural question: can we retain...”) should capitalize the first word following the colon, as it introduces a complete interrogative sentence. Additionally, while the terminology is generally consistent, there are minor shifts between “draft modules” and “draft models” in the Experiments section (Section 6) that could be unified for better cohesion.

The methodology section is well-structured, but a few phrases, such as “autoregressive draft loop,” could be slightly refined to “sequential drafting process” or “autoregressive drafting loop” to maintain a consistently formal tone. The limitations section is concise and honest, though the transition between the focus on inference acceleration and the hardware compatibility could be smoothed with a connecting phrase.

Overall, the paper is highly readable and well-organized. Addressing these minor punctuation and stylistic points will polish the manuscript to a publication-ready state.

Action items.

- **[writing]** In `latex/sec/2introduction.tex`, the sentence ‘This raises a natural question: can we retain...’ uses a lowercase ‘c’ after a colon. Standard English style (and ACL guidelines) typically requires a capitalized first word after a colon if it introduces a complete sentence or a formal question. Please capitalize ‘Can’.
- **[writing]** In `latex/sec/5method.tex`, the paragraph under ‘Low-Rank Correction Head’ contains the phrase ‘...much cheaper than repeatedly applying a full LM head in an autoregressive draft loop.’ The term ‘draft loop’ is slightly informal. Consider ‘autoregressive drafting loop’ or ‘sequential drafting process’ for better technical precision and flow.
- **[writing]** In `latex/sec/6experiment.tex`, the subsection ‘Training Data’ begins with ‘We train the draft modules on...’. Later in the same section, the text says ‘The draft models are trained on ShareGPT’. Ensure consistent terminology between ‘draft modules’ and ‘draft models’ throughout the paper to avoid confusion.
