

llmXive Automated Review of A Matter of TASTE: Improving Coverage and Difficulty of Agent Benchmarks

llmXive automated review panel

Please read first — this review is fully automated and not checked by any human. It is written by free, open-weight LLM agents that read the paper once, so **errors, misreadings, and inaccuracies are likely**. Nothing here has been verified by a person. Treat every point below as a fast, fallible first-pass signal — not an authoritative assessment.

How this review was produced

This Reviewed Preprint was read by a panel of specialist llmXive LLM reviewers. Each reviewer is deliberately confined to a *single narrow lens* — writing, logic, statistics, and so on — and does not comment outside it, so that distinct concerns are surfaced independently rather than blurred into one overall score. The panel runs *once* over the paper. Every reviewer's exact instructions are public in the [llmXive agent-prompt library](#); each section below also links the specific prompt it used.

This report is **advisory, automated feedback for the authors**. llmXive does not modify the paper, and **nothing is accepted or rejected** on its basis — every point below is a suggestion the authors are free to weigh. Each reviewer's section also names the underlying model that produced it.

This paper's panel (9 lenses): Claim Accuracy, Figure Critic, Jargon Police, Logical Consistency, Overreach, Safety Ethics, Scientific Evidence, Statistical Analysis, and Writing Quality. Each lens is described in its own section below, alongside the model and the exact prompt it used.

Claim Accuracy

Verifies factual claims against their citations — whether each cited source actually supports the claim attributed to it, and whether any claim is stated more strongly than its evidence permits.

Reviewer model: [qwen.qwen3.5-122b](#)

Prompt: `agents/prompts/paper_reviewer_claim_accuracy.md`

The paper makes several strong quantitative claims regarding performance drops and coverage improvements. While the data in the tables generally supports the direction of these claims, the textual summaries occasionally conflate distinct experimental conditions or overgeneralize domain-specific results.

Specifically, the Abstract and Section 5.1 present a performance range for Gemini-3-Flash (“0.82–0.94” on τ BV and “0.28–0.61” on the new benchmark) that aggregates results across two different user simulators (Gemini-3-Flash and GPT-5.2). Table 1 reveals that the high baseline (0.82–0.94) is achieved only when paired with the GPT-5.2 user, while the low baseline (0.56–0.72) occurs with the Gemini-3-Flash user. Similarly, the new benchmark scores vary significantly by user. Presenting these as a single continuous range obscures the impact of the user simulator variable and exaggerates the apparent saturation on the original benchmark for the specific agent-user pair being tested.

Additionally, the claim of a “124%” increase in Weighted Edit Distance (Section 5.2) is derived exclusively from the Airline domain (Table A1: 3.76 to 8.42). The Retail and Telecom domains show significantly lower increases (44% and 6%, respectively). While “up to” is technically accurate, the phrasing suggests a uniform improvement across all domains, which is not supported by the data.

Finally, the recall metrics for the Verifier Agent (Section 5.3) lack a defined denominator. It is unclear if recall is calculated against the set of all generated tasks or only those deemed valid by an external oracle. This ambiguity prevents a precise assessment of the verifier’s effectiveness.

These are primarily issues of precision in reporting rather than fundamental scientific flaws, but they require correction to ensure the claims accurately reflect the underlying data.

Action items.

- **[writing]** In the Abstract and Section 5.1, the claim that Gemini-3-Flash drops from ‘0.82–0.94’ to ‘0.28–0.61’ is misleading. Table 1 shows the 0.82–0.94 range applies only to the GPT-5.2 user simulator, while the 0.28–0.61 range applies to the Gemini-3-Flash user simulator. The text implies a single agent performance range across both conditions, conflating the user simulator variable. Clarify that these are distinct experimental conditions.
- **[writing]** Section 5.2 claims ‘Weighted edit distance (WED) increases up to 124%’. Table A1 shows the Airline domain WED intra increases from 3.76 to 8.42 (124%), but the Retail domain increases from 4.89 to 7.07 (44%) and Telecom from 6.63 to 7.05 (6%). The claim ‘up to 124%’ is technically true but omits that this is domain-specific. Specify that the 124% figure applies specifically to the Airline domain to avoid overgeneralization.
- **[writing]** Section 5.3 states ‘The verifier agent attains precision 1.0 (Airline) / 0.97 (Retail) and recall 0.75 / 0.83’. The text does not specify the denominator for recall (e.g., total valid tasks vs. total generated tasks). Without this context, the recall metric is ambiguous. Define the base set used for calculating recall to ensure the claim is verifiable.

Figure Critic

Inspects each figure directly — the rendered image alongside its caption — for clarity, axis labels and units, color choices, legibility at print scale, and whether the figure earns its place. This lens runs on a vision-capable model.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_figure_critic.md

Figure 1

The figure displays k-medoids clusters but fails to show the unweighted edit distance comparison promised in the caption, and it lacks a legend to define the color coding for tool types.

Figure 2

The figure content does not match the caption; the described ‘Airline Tool Frequency’ panel is missing, replaced by a second row of WED/TTR metrics, and the caption contains broken cross-references and undefined terms.

Figure 3

Figure 3 presents a clear visual comparison of accuracy across task difficulties, but it is scientifically incomplete due to a missing y-axis label, unlabeled y-ticks on the right panel, and undefined percentage deltas.

Figure 4

Figure 4 effectively illustrates the three-stage TASTE method visually, but the caption is severely broken with missing variable names and broken LaTeX syntax, rendering the scientific claims in the text unintelligible.

Figure 5

The figure fails to match its caption by omitting the described ‘Right’ panel (Task Evolution). Additionally, the x-axis labeling is inconsistent and the ‘OFF/ON’ bar categories are undefined, making the chart difficult to interpret.

Figure 6

Figure 6 is critically incomplete as it only displays one of the two required panels (retail vs. telecom) mentioned in the caption. Additionally, the caption has a missing baseline name and the single visible panel lacks clear labeling for the comparison distribution.

Action items.

- **[science]** Figure 1: The caption states the figure compares weighted vs. unweighted edit distance, but the image only displays one set of clusters (Cluster A, B, C) without a corresponding second panel for the unweighted comparison.
- **[writing]** Figure 1: The caption claims chips are colored by tool type (read, write, generic), but there is no legend or key provided in the figure to map the specific colors (yellow, pink, grey) to these categories.
- **[science]** Figure 2: The caption describes a ‘Right’ panel for ‘Airline Tool Frequency’, but the rendered image contains four panels (WED Gold, TTR Gold, WED Simulations, TTR Simulations) and lacks the described tool frequency distribution.
- **[science]** Figure 2: The caption mentions ‘*BV* distribution’ and ‘Other domains in Figure .’, but the chart labels use ‘rBV’ and ‘Ours’, and the cross-reference is broken/empty.
- **[science]** Figure 3: The y-axis lacks a label (e.g., ‘Accuracy (%)’) and the right panel’s y-axis has no tick labels, making the absolute performance values impossible to read.
- **[science]** Figure 3: The caption mentions ‘using 0.5 thresholds’ but does not define the units or scale for the ‘write ratio’ x-axis categories (read-heavy vs. write-heavy), nor does it explain the ‘middle band dropped’ methodology.
- **[writing]** Figure 3: The red percentage values (e.g., ‘-36%’) are placed directly on the bars without a legend or caption explanation defining what these deltas represent (e.g., relative drop from short/read-heavy baseline).
- **[fatal]** Figure 4: The caption contains broken LaTeX syntax (2 -Bench’, ‘*BV*’) and missing variable names (e.g., ‘unlike *BV*, is non-saturated’), making the text unreadable and the comparison subject undefined.
- **[science]** Figure 4: The bar chart labels use ‘ τ BV’ and ‘Ours’, but the caption refers to ‘*BV*’ and ‘Verified’; the figure fails to explicitly define which domain corresponds to ‘Ours’ or ‘Verified’ in the visual legend.
- **[writing]** Figure 4: The caption references ‘see .’ with a missing citation number, failing to direct the reader to the specific figure or section quantifying the Type-Token Ratio (TTR).
- **[fatal]** Figure 5: The caption describes a ‘Left’ panel (n-gram Model) and a ‘Right’ panel (Task Evolution), but the rendered image contains only a single chart. The ‘Task Evolution’ data mentioned in the caption is missing.
- **[science]** Figure 5: The x-axis labels are inconsistent and confusing. The first group is labeled ‘Uniform Iteration k=0’, while subsequent groups are labeled ‘k=400’, ‘k=800’, and ‘k=3000’. The ‘Uniform’ label does not fit the ‘Iteration k’ pattern, and the ‘OFF/ON’ labels under the bars are not defined in the caption or legend.
- **[writing]** Figure 5: The x-axis labels are rotated and crowded, making them difficult to read. The text ‘Init C+ with n-grams from:’ and ‘Train with C-:’ are placed awkwardly above the bars without clear pointers or grouping lines.

- **[fatal]** Figure 6: The caption states ‘Per-tool relative frequency on the retail and telecom domains’ and mentions ‘each panel’s legend’, but the rendered image shows only a single panel (likely retail) and lacks the second panel (telecom) entirely.
- **[science]** Figure 6: The caption claims tools are ‘ordered within each panel by task frequency’, but the y-axis labels (e.g., ‘get_order_details’ at the top with highest frequency, ‘list_all_product_types’ at the bottom) appear to be ordered by frequency, yet the caption implies a comparison against a baseline (likely BV) which is not explicitly labeled in the legend or axis.
- **[writing]** Figure 6: The caption contains a placeholder ‘comparing against ;’ with a missing baseline name (likely ‘BV’ based on context from other figures), making the comparison unclear.

Jargon Police

Flags needless jargon: terms with plainer equivalents, acronyms not defined at first use, and passages that needlessly exclude non-specialist readers.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_jargon_police.md

The manuscript relies heavily on domain-specific jargon and undefined acronyms that hinder accessibility for a broader audience. In the Abstract, “TTR” is used without definition; it should be spelled out as “Type-Token Ratio” immediately. Similarly, “WED” appears in Section 4.2 without expansion; “Weighted Edit Distance” must be stated first.

The term “medoids” is used frequently in Section 3.2 and the algorithms. While standard in clustering literature, it is not common knowledge outside that subfield. The authors should either define it as “representative cluster centers” or provide a brief parenthetical explanation upon first use.

In Section 2, the phrase “gold final state” and “gold tool-call sequence” uses “gold” as a synonym for “ground truth.” While common in ML, explicitly stating “ground truth (gold) state” once would improve clarity.

Most critically, Section 5 introduces “\passone” and “\passthree” as metrics. These appear to be LaTeX macros for “pass@1” and “pass@3” but are presented as undefined symbols in the text. The text must explicitly state “pass@1 (passone)” and “pass@3 (passthree)” or simply use the standard notation “pass@1” and “pass@3” to ensure the metrics are understood without needing to inspect the LaTeX source.

Finally, terms like “Adaptive Contrastive n-gram model” and “Levenshtein distance” are used without brief context for what they measure or why they are chosen, assuming a level of prior knowledge that may not exist for all readers. A single sentence explaining the intuition behind the contrastive sampling or the weighted distance would significantly lower the barrier to entry.

Action items.

- **[writing]** The manuscript relies heavily on domain-specific jargon and undefined acronyms

that hinder accessibility for a broader audience. In the Abstract, “TTR” is used without definition; it should be spelled out as “Type-Token Ratio” immediately. Similarly, “WED” appears in Section 4.2 without expansion; “Weighted Edit Distance” must be stated first. The term “medoids” is used frequently in Section 3.2 and the algorithms. While standard in clustering literature, it is not common knowledge outside that

Logical Consistency

Checks that each conclusion follows from its premises, flagging internal contradictions and causal claims that lack a stated supporting mechanism.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_logical_consistency.md

The paper presents a coherent methodology for generating benchmarks, but there are minor logical gaps in how specific claims are supported by the stated mechanisms.

First, in Section 5 (TASTE), the authors list “Validity” as a target of Stage 1 (Tool Sequence Sampling). Logically, sampling diverse sequences does not ensure validity; validity is explicitly enforced in Stage 3 via the Verifier agent. The text implies the sampling stage contributes to validity, but the mechanism described (contrastive n-gram) only targets diversity and plausibility, not solvability. This conflation of “plausible” and “valid” weakens the logical flow of the three-stage design.

Second, the claim that the benchmark demonstrates “saturation” of existing models (Abstract, Results) relies on the premise that the performance drop is due to the models hitting a capability ceiling on *this specific type* of task, rather than simply failing on a distributional shift. While the paper shows increased difficulty (longer sequences, more tools), it does not explicitly disentangle whether the drop is due to the *complexity* of the new tasks or the *novelty* of the tool combinations. If the drop is purely due to novelty, the “saturation” claim is less robust. The logic would be strengthened by an analysis showing that models fail even on tasks with familiar tool combinations but higher structural difficulty.

Finally, the link between the clustering metric (Weighted Edit Distance) and the resulting task difficulty is asserted but not fully mechanistically explained. The paper states that clustering selects representative sequences to ensure coverage. However, it does not explicitly argue why the *medoids* of these clusters, once evolved, are necessarily harder than non-medoid samples or random samples. The logical step from “representative of the space” to “maximally difficult” is missing; the difficulty seems to come from the *evolution* stage, not the clustering stage. Clarifying that clustering ensures *coverage* while evolution ensures *difficulty* would resolve this logical ambiguity.

Action items.

- **[writing]** The paper presents a coherent methodology for generating benchmarks, but there are minor logical gaps in how specific claims are supported by the stated mechanisms. Overreach

Looks for over-claiming: conclusions extrapolated beyond what the data, methods, or scope justify, and whether the paper states its limitations honestly.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_overreach.md

The paper makes several strong claims regarding the saturation of existing benchmarks and the superior coverage of the proposed TASTE benchmark. While the methodology is sound, the manuscript occasionally extrapolates beyond the strict evidence provided by the single-run experimental setup.

First, the Abstract and Introduction assert that existing benchmarks are “saturated” and that agents exhibit “severe drops” in performance. The data supports a large relative decrease in scores (e.g., -52.8% for Gemini-3-Flash). However, the NeurIPS Checklist explicitly states: “Table 1 reports point estimates... without error bars due to API-cost constraints.” Without statistical significance testing (e.g., bootstrapping or multiple seeds), claiming “saturation” is an overreach. The observed drops could theoretically be influenced by variance in the specific task instances or the stochastic nature of the LLMs, rather than a fundamental structural saturation. The authors should qualify these claims, perhaps stating that agents “show significant performance degradation” rather than definitively proving saturation, or acknowledge the lack of statistical validation as a limitation.

Second, the claim that TASTE “doubles coverage” (Abstract, Section 5.2) is derived from metrics like Weighted Edit Distance (WED) increasing by 124% and Type-Token Ratio (TTR) by 111%. While these numbers are impressive, they are relative to the specific “tau-Bench Verified” baseline. The phrasing “doubles coverage” suggests a universal improvement in benchmark quality. The evidence only supports that TASTE tasks are structurally more diverse *than the specific subset of tau-Bench Verified tasks used for comparison*. The claim should be more precise, e.g., “TASTE tasks exhibit more than double the structural diversity compared to the tau-Bench Verified baseline.”

Finally, the Conclusion states that TASTE “could also generate training data.” This is a speculative claim not supported by the paper’s data, which focuses entirely on evaluation. There is no evidence presented regarding the quality of TASTE-generated tasks for *training* (e.g., do models trained on TASTE data generalize better?). This extrapolation should be removed from the conclusion or explicitly framed as a direction for future work rather than an implication of the current results.

Action items.

- **[science]** The abstract and introduction claim ‘severe drops’ and that benchmarks are ‘saturated’ based on single-point estimates without statistical significance testing. The checklist explicitly admits to reporting point estimates without error bars due to cost. The

paper must temper claims of ‘saturation’ to reflect that the observed drops, while large, are not statistically validated against variance.

- **[writing]** The paper claims TASTE ‘doubles coverage’ (Abstract, Section 5.2) based on metrics like WED (+124%) and TTR (+111%). However, the baseline is a specific subset of tau-Bench (Verified). The claim of ‘doubling coverage’ implies a general property of the new benchmark, but the data only supports a comparison against this specific baseline. The scope of the claim should be restricted to the specific comparison made.
- **[writing]** The conclusion states TASTE ‘could also generate training data.’ This is a speculative extrapolation beyond the paper’s scope, which focuses exclusively on benchmark construction and evaluation. The paper provides no data on model performance improvements when trained on TASTE-generated data. This forward-looking claim should be removed or clearly labeled as future work.

Safety Ethics

Examines safety and ethics — dual-use risk, IRB/IACUC and consent concerns, potential for harm, data privacy, and conflicts of interest — aiming to be thorough but not alarmist.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_safety_ethics.md

The paper addresses the critical issue of benchmark saturation in LLM agent evaluation by proposing TASTE, a method to automatically synthesize diverse and difficult tasks. From a safety and ethics perspective, the work is generally sound in its intent to improve evaluation rigor, but it requires specific clarifications regarding the generation of adversarial content and the potential for dual-use.

The authors explicitly design the “Difficulty evolution” stage to introduce “adversarial patterns” such as “DB-grounded misdirection” and “policy enforcement” (Section 4.3, Algorithm 3). While the goal is to test agent robustness, the NeurIPS Checklist (Section e001) incorrectly marks “Broader impacts” and “Safeguards” as “NA”. This is a significant oversight. The methodology described—using LLMs to generate tasks specifically designed to confuse or bypass agent logic—could theoretically be repurposed (dual-use) to create training data for agents intended to evade safety filters, perform social engineering, or exploit system vulnerabilities. The authors must add a discussion in the “Broader Impacts” section addressing these potential misuse scenarios and the steps taken to mitigate them.

Furthermore, the generation of “decoy records” and “adversarial scenarios” (Section 4.3) carries a risk of inadvertently generating harmful content, such as personally identifiable information (PII), hate speech, or instructions for illegal activities, even within a simulated environment. The paper mentions a “Verifier agent” but does not detail the specific safety filters or content moderation protocols applied to the generated text before it is included in the benchmark. A statement confirming that the generated tasks were screened for harmful content (either via automated filters or manual inspection) is necessary to ensure the dataset does not propagate

safety violations.

Finally, while the paper notes the high cost of generation (\$725) and evaluation (\$520) (Section 5), this resource intensity limits the ability of the broader community to independently verify the safety and validity of the generated tasks. The authors should briefly acknowledge this limitation and discuss how their safety validation protocols could be adapted for lower-resource settings to ensure the benchmark remains a safe and verifiable community asset.

Overall, the paper’s safety posture is acceptable provided these specific gaps in the discussion of dual-use risks and content generation safeguards are addressed.

Action items.

- **[writing]** The NeurIPS Checklist (Section e001) marks ‘Broader impacts’ and ‘Safeguards’ as NA. Given the paper’s explicit goal of generating ‘adversarial’ tasks (e.g., ‘DB-grounded misdirection’, ‘policy enforcement’) to degrade agent performance, a discussion on dual-use risks is required. Specifically, address how this methodology could be misused to generate training data for agents designed to bypass safety filters or exploit system vulnerabilities.
- **[writing]** The ‘Verifier agent’ and ‘Evolution’ stages rely on LLMs to generate ‘decoy records’ and ‘adversarial patterns’ (Section 4.3, Algorithm 3). The paper states these are validated but does not detail safeguards against the generation of harmful content (e.g., PII, hate speech, or instructions for illegal acts) within the synthetic task scenarios. A statement confirming the implementation of content filters or manual review protocols for generated task text is needed.
- **[writing]** The paper reports evaluation costs of \$725 for generation and \$520 for evaluation (Section 5). While not a direct safety violation, the reliance on expensive API calls for generating adversarial benchmarks creates a barrier to entry that limits independent verification of safety claims. The authors should explicitly discuss the reproducibility of their safety/validity checks for the broader community given these resource constraints.

Scientific Evidence

Weights the strength of the scientific evidence: sample sizes, controls, replication, effect sizes, p-hacking risk, and robustness of the central claims to plausible alternative explanations.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_scientific_evidence.md

The paper presents a compelling methodology (TASTE) for addressing benchmark saturation in LLM agents, with a clear focus on coverage and difficulty. The experimental design is generally sound, utilizing a large pool of sampled sequences (N=2000) and clustering to ensure diversity. However, the scientific evidence supporting the central claims requires strengthening in three specific areas regarding statistical rigor and validity guarantees.

First, the lack of statistical significance testing is a critical gap. The NeurIPS Checklist (Item 7) admits to omitting error bars due to API costs, yet the main results (Table 1, Section 5.1) rely entirely on single-point estimates. LLM agent performance is notoriously stochastic; a single

run per task is insufficient to distinguish between a genuine capability gap and random variance. The reported drops (e.g., -52.8% for Gemini-3-Flash) are large, but without confidence intervals or a multi-seed evaluation, the robustness of these claims is unproven. The authors should re-run the evaluation with multiple seeds to provide error bars or perform a bootstrap analysis.

Second, the validity of the benchmark relies heavily on an LLM-based “Verifier agent” (Section 4.3). While the authors report high precision, the recall is only 0.75–0.83. This means a significant fraction of potentially valid tasks are discarded, or the verifier’s definition of “valid” is too strict. More concerning is the risk that the verifier itself hallucinates solvability. The claim that all tasks are “verifiable and have a reachable gold final state” is not fully supported by an LLM-only check. A manual audit of a random sample of tasks (both accepted and rejected) by human experts is necessary to confirm the ground truth.

Third, the “difficulty” of the evolved tasks is defined by the failure of other LLMs. This introduces a potential confound: if the evolution process (also LLM-driven) introduces nonsensical constraints or “hallucinated” logic that no agent can solve, the benchmark measures robustness to noise rather than genuine task complexity. The paper mentions “manual inspection of 15 failed tasks” (Checklist Item 15), but this sample size is too small to generalize. A human baseline evaluation on a subset of the evolved tasks would provide a crucial sanity check to ensure the difficulty is structural and not an artifact of the synthesis pipeline.

Addressing these points—specifically by adding statistical variance metrics and a human validation of the task validity/difficulty—would significantly strengthen the scientific evidence.

Action items.

- **[science]** Table 1 reports single-point estimates without confidence intervals. Re-run evaluations with multiple seeds ($n \geq 5$) per task or provide bootstrap CIs to validate that performance drops are not due to stochasticity.
- **[science]** The LLM-based Verifier has 0.75 recall, risking invalid tasks. Provide a human audit of a random sample of accepted/rejected tasks to confirm the ground truth validity of the benchmark.
- **[science]** Difficulty is defined by LLM failure, risking noise artifacts. Include a human baseline on a subset of evolved tasks to ensure difficulty is structural, not a generation artifact.

Statistical Analysis

Scrutinizes the statistics — appropriateness of tests, multiple-comparison handling, confidence intervals, model assumptions, and the reproducibility of the analyses.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_statistical_analysis.md

The paper presents a novel pipeline (TASTE) for generating agent benchmarks, but the statistical rigor of the evaluation results requires strengthening before the claims of “severe drops” and “improved coverage” can be fully substantiated.

Lack of Variance Estimates and Significance Testing The primary statistical concern

lies in Section 5 (Results) and Table 1. The authors report single-point accuracy scores (e.g., 0.34 vs 0.72) and calculate relative percentage changes. However, LLM performance is inherently stochastic; a single run per task does not capture the variance of the model’s behavior. The NeurIPS Checklist (Item 7) explicitly admits that “Table 1 reports point estimates... without error bars due to API-cost constraints.” While cost is a practical constraint, it does not negate the need for statistical rigor when making comparative claims. Without confidence intervals (CIs) or standard errors, it is impossible to determine if the observed performance drops are statistically significant or merely artifacts of random variation in the specific task samples or model seeds. The authors should either:

1. Perform a bootstrap analysis over the task set to generate 95% confidence intervals for the mean accuracy.
2. Run a subset of tasks with multiple seeds to estimate variance.
3. Explicitly reframe the results as “observed descriptive statistics” rather than definitive evidence of performance degradation, acknowledging the lack of statistical significance testing.

Clustering Parameter Sensitivity In Section 4.2, the authors employ K-medoids clustering with a weighted Levenshtein distance. The substitution costs (0.33 for same-group, 0.66 for same-type, 1.0 otherwise) are fixed hyperparameters. The statistical validity of the resulting “diverse” clusters depends heavily on these weights. There is no sensitivity analysis provided to show how robust the medoid selection and subsequent coverage metrics are to variations in these weights. A small ablation study or a theoretical justification for these specific values would improve the reproducibility and statistical soundness of the diversity claims.

Coverage Metrics Aggregation The coverage improvements (e.g., “+124% WED”) are reported as aggregate percentages. It is unclear if these are mean values across the dataset or values derived from the full set. Given the small sample sizes per domain (50-114 tasks), the distribution of these metrics (e.g., skewness in sequence lengths) should be reported to ensure the mean is a representative statistic.

In summary, while the methodology is sound, the statistical presentation of the results is currently insufficient to support the strong claims of benchmark saturation and difficulty. Addressing the lack of variance estimates is critical.

Action items.

- **[science]** Table 1 and Section 5 report point estimates for agent performance without confidence intervals or standard errors. Given the stochastic nature of LLM outputs and the single-run evaluation per task, statistical significance of the reported performance drops (e.g., -52.8%) cannot be assessed. Please add error bars (e.g., via bootstrapping over tasks or multiple seeds) or explicitly state the limitation regarding statistical significance in the checklist and text.
- **[science]** The NeurIPS Checklist (Item 7) explicitly states ‘Answer: No’ for statistical significance due to API costs. However, the paper makes strong comparative claims (e.g., ‘severe drops’) based on single-point estimates. To support these claims scientifically, the

authors must either provide variance estimates (e.g., 95% CIs) or reframe the results as descriptive statistics without implying statistical superiority/difference.

- **[science]** The clustering method (K-medoids) uses a weighted Levenshtein distance with fixed substitution costs (0.33, 0.66, 1.0). The sensitivity of the resulting medoids and subsequent task coverage to these specific weight choices is not analyzed. A brief ablation or justification for these weights would strengthen the statistical validity of the diversity claims.

Writing Quality

Reads the manuscript purely as prose — clarity, flow, sentence-level grammar, paragraph cohesion, and overall readability — setting the scientific content aside.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_writing_quality.md

The manuscript demonstrates a high level of technical sophistication, but the writing quality occasionally suffers from density and minor ambiguities that could impede rapid comprehension. The abstract is particularly dense, packing multiple metrics and results into single sentences. For instance, the notation “ $K = 50/114/114$ for Airline/Retail/Telecom” in the Abstract is syntactically compressed; while the mapping is inferable, explicitly stating “ $K=50$ for Airline, 114 for Retail, and 114 for Telecom” would improve clarity.

In Section 5 (Results), the presentation of performance drops (e.g., “0.82–0.94 $\rightarrow$ 0.28–0.61”) is visually striking but requires careful reading to distinguish whether these ranges reflect variations across user simulators or task difficulty buckets. A brief clarifying clause in the text would prevent misinterpretation. Additionally, the term “reverse task construction” used in the Introduction and Section 2 is slightly colloquial; “invert the task construction paradigm” might better suit the formal tone of the venue.

The mathematical notation in Section 3 is generally sound, though the use of “ $\equiv$ ” for state equivalence should be explicitly defined or justified if it differs from standard equality, ensuring readers do not confuse it with logical equivalence. Overall, the prose is concise and professional, but these minor adjustments would significantly enhance readability and precision.

Action items.

- **[writing]** In the Abstract, the notation ‘ $K = 50/114/114$ ’ is ambiguous. Clarify which value corresponds to which domain (Airline, Retail, Telecom) to prevent reader confusion.
- **[writing]** Section 5 (Results) and the Abstract contain dense numerical ranges (e.g., ‘0.82-0.94 $\rightarrow$ 0.28-0.61’). Ensure the text explicitly states whether these ranges represent performance across different user simulators or task subsets to avoid misinterpretation.
- **[writing]** The phrase ‘reverse task construction’ in the Introduction and Section 2 is slightly informal. Consider rephrasing to ‘invert the task construction paradigm’ or ‘reverse the standard task generation pipeline’ for greater academic precision.
- **[writing]** In Section 3, the definition of the reward function uses the symbol ‘ $\equiv$ ’ for state

equivalence. Ensure this notation is defined or standard in the context of the paper, or use ‘=’ if the states are strictly identical, to avoid ambiguity.
