

llmXive Automated Review of Code as Agent Harness

llmXive automated review panel

Please read first — this review is fully automated and not checked by any human. It is written by free, open-weight LLM agents that read the paper once, so **errors, misreadings, and inaccuracies are likely**. Nothing here has been verified by a person. Treat every point below as a fast, fallible first-pass signal — not an authoritative assessment.

How this review was produced

This Reviewed Preprint was read by a panel of specialist llmXive LLM reviewers. Each reviewer is deliberately confined to a *single narrow lens* — writing, logic, statistics, and so on — and does not comment outside it, so that distinct concerns are surfaced independently rather than blurred into one overall score. The panel runs *once* over the paper. Every reviewer's exact instructions are public in the [llmXive agent-prompt library](#); each section below also links the specific prompt it used.

This report is **advisory, automated feedback for the authors**. llmXive does not modify the paper, and **nothing is accepted or rejected** on its basis — every point below is a suggestion the authors are free to weigh. Each reviewer's section also names the underlying model that produced it.

This paper's panel (8 lenses): Claim Accuracy, Figure Critic, Jargon Police, Overreach, Safety Ethics, Scientific Evidence, Statistical Analysis, and Writing Quality. Each lens is described in its own section below, alongside the model and the exact prompt it used.

Claim Accuracy

Verifies factual claims against their citations — whether each cited source actually supports the claim attributed to it, and whether any claim is stated more strongly than its evidence permits.

Reviewer model: [qwen.qwen3.5-122b](#)

Prompt: [agents/prompts/paper_reviewer_claim_accuracy.md](#)

The manuscript makes several specific quantitative claims regarding the performance of cited systems (e.g., success rates, precision metrics, iteration limits) that require verification against

the primary sources. Specifically, the claims in Section 4.1.1 regarding LingmaAgent (16.9% autonomous, 43.3% with intervention), Section 4.1.4 regarding El Agente Q (87% success) and Virtual Lab (92 nanobodies, 2 validated), and Section 4.1.5 regarding AIDE (16.9% bronze rate) must be cross-referenced with the full text of `ma2025alibaba`, `li2026advances`, `Zou_2025`, `swanson2025virtual`, and `chan2025mlebenchevaluatingmachinelearning` to ensure the numbers are accurate and correctly attributed. Additionally, the claim in Section 4.2.1 that QualityFlow achieves 98%+ precision with “Imagined Execution” and the specific 10-round termination limit for ChatDev in Section 4.2.1 need confirmation in `Hu2025QualityFlow` and `Qian2023ChatDev` respectively. While the citations are present, the specific numeric values attributed to them are not verifiable from the provided snippets alone and must be checked to prevent potential hallucination or misattribution of results.

Action items.

- **[writing]** Section 4.1.1 claims LingmaAgent resolves 16.9% of issues autonomously and 43.3% with intervention, citing `ma2025alibaba` and `li2026advances`. Verify these specific percentages in the cited sources, as the text does not explicitly state these exact figures in the provided snippets.
- **[writing]** Section 4.1.4 states El Agente Q exceeds 87% success and Virtual Lab designed 92 nanobodies with 2 validated, citing `Zou_2025` and `swanson2025virtual`. Confirm these specific numbers are present in the cited works, as the provided bibliography entries lack abstracts or results sections.
- **[writing]** Section 4.1.5 claims AIDE achieves 16.9% bronze medal rate on MLE-bench, citing `huang2024mlagentbenchevaluatinglanguageagents` and `chan2025mlebenchevaluatingmachinelearning`. Ensure the 16.9% figure is explicitly attributed to AIDE in these sources and not a general benchmark statistic.
- **[writing]** Section 4.2.1 claims QualityFlow uses ‘Imagined Execution’ with 98%+ precision, citing `Hu2025QualityFlow`. Verify that the cited paper explicitly reports this precision metric for the imagined execution component.
- **[writing]** Section 4.2.1 states ChatDev terminates after 10 rounds or fixed phases. Verify this specific iteration limit (10) is a hard constraint defined in `Qian2023ChatDev`, as the provided text does not confirm the exact number.

Figure Critic

Inspects each figure directly — the rendered image alongside its caption — for clarity, axis labels and units, color choices, legibility at print scale, and whether the figure earns its place. This lens runs on a vision-capable model.

Reviewer model: `qwen.qwen3.5-122b`

Prompt: `agents/prompts/paper_reviewer_figure_critic.md`

Figure 1

Figure 1 is a clear and well-structured taxonomy diagram that effectively visualizes the hierarchy of the ‘Code as Agent Harness’ concept. The layout logically flows from the high-level loop to specific mechanisms, interfaces, and applications, with all text legible and icons distinct.

Figure 2

Figure 2 is a clear and well-organized infographic that effectively visualizes the five emerging domains of code as an agent harness. The layout is uncluttered, the icons are distinct, and the text labels are legible, fully supporting the caption’s description.

Figure 3

Figure 3 provides a clear visual roadmap of agent harness mechanisms across five categories, but it suffers from significant ambiguity due to repeated entries (e.g., MapCoder, AgentCoder, OpenHands, SWE-Agent) appearing in multiple rows without visual distinction or explanation.

Figure 4

Figure 4 is a clear and well-structured diagram that effectively visualizes the taxonomy of planning mechanisms for agent harnesses. The four categories are distinct, the icons are intuitive, and the layout aligns perfectly with the provided caption.

Figure 5

Figure 5 is a clear and well-organized schematic that effectively illustrates the taxonomy of memory and context engineering mechanisms. The visual distinction between different memory types (Working, Semantic, Experiential, etc.) is intuitive, and the diagram aligns perfectly with its caption.

Figure 6

Figure 6 is a clear, well-organized schematic that effectively illustrates four distinct categories of tool use for agent harnesses. The visual icons and accompanying text labels are legible and directly support the caption’s description of the taxonomy.

Figure 7

Figure 7 is a clear, well-organized schematic that effectively visualizes the taxonomy of code as an agent harness. The three distinct columns (Reasoning, Acting, Environment Modeling) are clearly labeled with icons and text, and the bottom row provides concrete examples of the underlying artifacts (Executor, Robot, Repo, etc.). The visual hierarchy and color coding support the caption’s description of connecting agents to these three core functions.

Figure 8

The figure provides a clear visual taxonomy of works by role, but it contains a significant scientific error by listing future publication years (2025-2026) as if they are established works. Additionally, the reliance on unlabelled logos for authorship identification reduces accessibility.

Figure 9

Figure 9 is a clear, well-structured diagram illustrating the ‘Harness Control through the Plan, Execute, and Verify Loop’ via four distinct components. The visual icons, flow arrows, and descriptive text labels effectively communicate the concepts of Static Analysis, Sandboxed Execution, Deterministic Verification, and Permissioned State Transition without ambiguity.

Figure 10

The figure provides a clear, high-level schematic of the adaptive harness optimization process with distinct steps and icons. However, it contains a minor formatting error where a raw LaTeX section reference command is visible in the title area.

Figure 11

Figure 11 is a clear and well-structured conceptual diagram that effectively visualizes the taxonomy of multi-agent orchestration. The layout logically contrasts single-agent limitations with multi-agent solutions, and all components are clearly labeled and consistent with the provided caption.

Figure 12

The figure provides a clear visual roadmap of multi-agent orchestration works, but the caption contains a terminology mismatch (‘coordination’ vs ‘Orchestration’) and lacks a legend defining the institutional logos used as markers.

Action items.

- **[science]** Figure 3: ‘MapCoder’ appears in both the ‘Planning’ and ‘Tool Use’ rows, but the figure provides no visual distinction (e.g., color, icon, or label) to indicate if it is the same work or different variants, creating ambiguity.
- **[science]** Figure 3: ‘AgentCoder’ appears in both the ‘Tool Use’ and ‘Control’ rows with the same logo and year (2023), yet the figure lacks a mechanism to clarify if this is a single work spanning categories or a duplicate entry.
- **[science]** Figure 3: ‘OpenHands’ appears in both the ‘Tool Use’ and ‘Optimization’ rows with the same logo and year (2025), but the figure does not visually distinguish between these instances or explain the relationship.
- **[science]** Figure 3: ‘SWE-Agent’ appears in both the ‘Memory’ and ‘Control’ rows with the same logo and year (2024), but the figure lacks a legend or visual cue to clarify if this is the

same work or distinct variants.

- **[writing]** Figure 3: The timeline at the top uses colored dots (2023-2026) but lacks a legend defining what the colors represent or how they map to the specific years listed below.
- **[science]** Figure 8: The timeline includes publication years 2025 and 2026 (e.g., ‘CodePRM (2025)’, ‘ExecVerify (2026)’) for works that have not yet been published, which is factually impossible for a scientific roadmap of existing literature.
- **[writing]** Figure 8: The logos for various institutions and companies (e.g., Google, NVIDIA, TUM) are used to identify the authors of the works but are not defined in a legend or caption, requiring external knowledge to interpret.
- **[writing]** Figure 10: The top-right text ‘(§Sec. 3.5)’ is a raw LaTeX cross-reference command that was not rendered into a clean section link or title, indicating a compilation or formatting oversight.
- **[writing]** Figure 12: The caption lists ‘adaptive coordination’ as the fourth category, but the figure’s y-axis label reads ‘Adaptive Orchestration’; align the text to match the visual label.
- **[writing]** Figure 12: Several logos (e.g., ‘sea | AI lab’, ‘aws’) are used as markers without a legend or explicit definition in the caption explaining their role as institutional affiliations.

Jargon Police

Flags needless jargon: terms with plainer equivalents, acronyms not defined at first use, and passages that needlessly exclude non-specialist readers.

Reviewer model: `qwen.qwen3.5-122b`

Prompt: `agents/prompts/paper_reviewer_jargon_police.md`

The manuscript suffers from significant jargon overuse, particularly in the introduction and the “Open Problems” sections, where the authors coin or repurpose terms without sufficient definition for a general audience. The central term “harness” is used as a proper noun (“Code as Agent Harness”) throughout, yet the text never explicitly defines it as the “runtime infrastructure and execution environment” distinct from the model itself. This forces the reader to infer the meaning from context, which is a barrier to entry.

Specific instances of undefined or opaque terminology include “organicity” (Section 5.1.1), which appears to be a neologism for “adherence to project conventions” but is presented as a standard metric. Similarly, “cybernetic governor” (Section 3.4) uses historical control theory jargon where “safety governor” or “control mechanism” would be clearer. Acronyms such as “PEV” (Plan-Execute-Verify), “AHE” (Agentic Harness Engineering), “MCP” (Model Context Protocol), and “HITL” (Human-in-the-Loop) are introduced without explicit expansion at their first occurrence in the main text, violating standard readability practices.

The text frequently relies on dense, abstract phrasing like “latent state,” “semantic conflict resolution,” and “epistemic weight” without grounding these in plain English explanations. For instance, the discussion of “belief-state divergence” ($|B_k - S_k|$) in Section 4.1 assumes the

reader understands the specific formalism of belief states in multi-agent systems without a brief, intuitive explanation. The paper needs a dedicated glossary or a more rigorous “Definition” section early on to establish the vocabulary, and a systematic pass to replace coined terms with standard, descriptive language.

Action items.

- [science] The manuscript suffers from significant jargon overuse, particularly in the introduction and the “Open Problems” sections, where the authors coin or repurpose terms without sufficient definition for a general audience. The central term “harness” is used as a proper noun (“Code as Agent Harness”) throughout, yet the text never explicitly defines it as the “runtime infrastructure and execution environment” distinct from the model itself. This forces the reader to infer the meaning from context, wh

Overreach

Looks for over-claiming: conclusions extrapolated beyond what the data, methods, or scope justify, and whether the paper states its limitations honestly.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_overreach.md

The manuscript presents a comprehensive survey on “Code as Agent Harness,” but several sections exhibit over-claiming by extrapolating specific findings to general principles or presenting hypothetical future states as established facts.

First, in Section 4.1 (“Patterns and Trends”), the authors state: “Self-Collaboration and QualityFlow show LLM-simulated execution achieves 98%+ precision/recall.” This phrasing implies a general capability of simulated execution across the field. However, this metric is likely specific to the *QualityFlow* system’s “Imagined Execution” module. Attributing this high precision to the broader concept of “LLM-simulated execution” without qualifying that it is a result of a specific, gated mechanism overstates the current state of the art. The claim should be restricted to the specific system or explicitly framed as a potential upper bound rather than a general achievement.

Second, the assertion in Section 4.1 that “No system fully unifies both” repository-based and execution-based representations is a definitive negative claim. While the survey likely covers the major works, asserting a total absence of such systems without a formal proof or exhaustive enumeration risks over-claiming the survey’s completeness. It is safer to phrase this as “No *major* system surveyed fully unifies...” or to explicitly list the systems considered to justify the gap.

Third, the manuscript frequently cites systems like “GPT-5-Codex” and “GPT-5.1-Codex-Max” (Section 5.1) as if they are existing, deployed entities with specific training data characteristics. Given the paper’s 2026 context, these appear to be hypothetical or future projections. Presenting them as factual, existing systems that “are explicitly trained on long-horizon, multi-turn coding interactions” constitutes an over-claim of current reality. The authors must distinguish between existing systems and projected/future capabilities to maintain scientific

rigor.

Finally, the claim that “Implicit convergence... is the most prevalent pattern” (Section 4.2) is a strong quantitative assertion. While likely true based on the authors’ reading, it should be supported by a brief quantitative breakdown of the surveyed systems (e.g., “X out of Y systems surveyed rely on implicit convergence”) rather than a qualitative generalization, to avoid over-claiming the statistical dominance of this pattern.

Action items.

- **[science]** The claim that ‘LLM-simulated execution achieves 98%+ precision/recall’ (Section 4.1, Patterns and Trends) is presented as a general fact without a specific citation or scope definition. This risks over-generalizing results from a single method (QualityFlow) to the entire field of simulated execution. Please clarify the source and limit the claim to the specific system studied.
- **[writing]** The statement that ‘No system fully unifies both’ repository-based and execution-based representations (Section 4.1, Patterns and Trends) is a strong negative claim. Given the breadth of the survey, the authors should either provide a definitive list of excluded systems or soften the language to ‘No major system surveyed fully unifies...’ to avoid over-claiming completeness.
- **[writing]** The paper cites ‘GPT-5-Codex’ and ‘GPT-5.1-Codex-Max’ (Section 5.1) as existing systems trained on long-horizon interactions. As these refer to unreleased or hypothetical model versions (given the 2026 date context), the authors must explicitly state these are projections or future work, rather than presenting them as established empirical facts to avoid over-claiming current capabilities.

Safety Ethics

Examines safety and ethics — dual-use risk, IRB/IACUC and consent concerns, potential for harm, data privacy, and conflicts of interest — aiming to be thorough but not alarmist.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_safety_ethics.md

The manuscript “Code as Agent Harness” provides a comprehensive taxonomy of code-centric agentic systems. From a safety and ethics perspective, the paper correctly identifies the shift from model-centric to harness-centric reliability, emphasizing sandboxing, verification, and human-in-the-loop (HITL) gates (Sections 3.4 and 4.3). However, the treatment of safety remains largely technical (i.e., preventing code execution errors) rather than addressing broader ethical and dual-use risks.

First, while the paper mentions “safety governance” and “capability primitives” (Section 4.1), it lacks a dedicated discussion on **dual-use risks**. The ability of these harnesses to autonomously generate, test, and deploy code at scale significantly lowers the barrier for creating malware, exploiting vulnerabilities, or conducting supply chain attacks. The survey should explicitly address how the proposed frameworks mitigate these risks, such as through intent verification,

malicious code detection in the “Verify” phase, or ethical constraints on the “Action” interface.

Second, regarding **data privacy and consent**, the paper cites numerous benchmarks (e.g., SWE-bench, SWE-Lancer) and systems trained on large code corpora. There is insufficient discussion on the ethical implications of training these agents on potentially proprietary or private code, or the risk of agents memorizing and regurgitating sensitive information (e.g., API keys, PII) found in repositories. The “Memory” section (Sec 3.2) touches on context management but does not address the ethical necessity of filtering sensitive data from the agent’s memory or training set.

Third, in the context of **autonomous scientific discovery** (Section 4.4), the paper describes agents that design and execute physical experiments (e.g., chemical synthesis, protein design). While it mentions “safety boundaries,” it does not sufficiently detail the ethical protocols required to prevent physical harm or the misuse of these systems for creating hazardous materials. The distinction between software sandboxing and physical safety governance needs to be sharper.

Finally, the discussion on **accountability** (Section 4.5) is promising but brief. As agents become more autonomous, the “black box” nature of their decision-making in the “Plan-Execute-Verify” loop raises questions about liability for errors or malicious actions. The paper should expand on how the “harness” can provide auditable trails that satisfy legal and ethical accountability standards, particularly in high-stakes domains like finance or healthcare.

In summary, while the technical safety mechanisms are well-covered, the manuscript requires a more explicit and rigorous treatment of dual-use risks, data ethics, and physical safety governance to be complete.

Action items.

- **[writing]** The paper discusses ‘Human-in-the-Loop Safety’ and ‘Sandboxed Execution’ extensively (Sec 3.4, 4.3) but lacks a dedicated Ethics/Safety section detailing specific mitigation strategies for dual-use risks (e.g., autonomous code generation for malware, supply chain attacks). Explicitly address how the proposed harness prevents or detects malicious intent in generated code.
- **[writing]** In Section 4.1 (Code Assistants), the paper cites ‘solution leakage’ in benchmarks (e.g., SWE-bench). The review must clarify the ethical implications of training agents on data that may contain private or proprietary code, and whether the survey addresses data provenance and consent for the training corpora of the cited systems.
- **[writing]** Section 4.3 mentions ‘Self-Driving Labs’ and ‘Scientific Discovery’ where agents execute physical experiments. The manuscript needs to explicitly discuss safety protocols for physical harm (e.g., chemical synthesis, robotics) and the ethical boundaries of autonomous experimentation, rather than treating safety only as a software sandboxing issue.

Scientific Evidence

Weights the strength of the scientific evidence: sample sizes, controls, replication, effect sizes, p-hacking risk, and robustness of the central claims to plausible alternative explanations.

Reviewer model: `qwen.qwen3.5-122b`

Prompt: `agents/prompts/paper_reviewer_scientific_evidence.md`

The manuscript “Code as Agent Harness” presents a comprehensive taxonomy of code-centric agentic systems. From a scientific evidence perspective, the primary concern is the reliance on point estimates and qualitative assertions without sufficient statistical grounding or experimental context.

While the paper synthesizes a vast amount of literature, it frequently cites specific performance metrics (e.g., “98%+ precision” for QualityFlow in Section 4.2, “16.9% bronze medal rate” for AIDE in Section 5.1, “41 of 58” compounds synthesized by A-Lab in Section 5.1) without detailing the sample sizes (N), the specific benchmark versions, or the statistical significance of these results. In a survey context, this is acceptable only if the cited numbers are directly linked to the primary source’s rigorous statistical analysis. However, the text often presents these figures as definitive facts without clarifying the experimental conditions (e.g., number of runs, variance, or control baselines). For instance, the claim that “best step-level attribution accuracies” range from 14–53% (Section 5.1) lacks a clear definition of the evaluation protocol or the specific datasets used, making it difficult to assess the robustness of this range against potential selection bias or p-hacking in the cited works.

Furthermore, the paper makes strong claims about the efficacy of “simulated execution” (Section 4.2) and “imagined execution” achieving high precision, but does not provide quantitative evidence of the divergence between these simulations and real-world execution. Without a comparative analysis of failure modes or error rates between simulated and actual environments, the claim that simulation is a sufficient proxy for verification remains an unverified hypothesis rather than a supported conclusion. The discussion on “oracle adequacy” (Section 6.1) correctly identifies this as a bottleneck, yet the paper itself relies on the very metrics it critiques without providing the necessary statistical context to validate them.

To strengthen the scientific evidence, the authors should:

1. Explicitly cite the sample sizes and experimental designs (e.g., number of tasks, runs, or agents) for every quantitative claim.
2. Clarify the statistical significance or confidence intervals for performance metrics where available in the primary sources.
3. Provide a brief summary of the evaluation protocols for the benchmarks mentioned to ensure reproducibility and context.
4. Include a quantitative comparison or a specific citation regarding the gap between simulated and real-world execution to support claims about simulation fidelity.

The paper is otherwise well-structured, but the lack of statistical rigor in presenting evidence undermines the reliability of its central claims regarding system performance and efficacy.

Action items.

- **[science]** The manuscript cites specific quantitative performance metrics (e.g., ‘98%+ precision’ for QualityFlow, ‘16.9% bronze’ for AIDE, ‘41 of 58’ compounds for A-Lab) without

providing the underlying sample sizes, confidence intervals, or statistical significance tests. For a survey paper, these claims require explicit citation to the primary source’s statistical analysis or a summary of the experimental design (N, controls) to verify robustness.

- **[science]** Several claims regarding ‘state-of-the-art’ performance or ‘best accuracy’ (e.g., failure attribution accuracy of 14-53%) lack a clear definition of the evaluation protocol or the specific benchmark versions used. Without specifying the test sets and baseline comparisons, these ranges are difficult to interpret as robust scientific evidence rather than anecdotal observations.
- **[science]** The paper discusses ‘simulated execution’ achieving high precision but does not quantify the divergence between simulated and real-world execution in terms of error rates or specific failure modes. A brief quantitative comparison or a citation to a study that explicitly measures this gap is needed to support the claim that simulation is a sufficient proxy for verification.

Statistical Analysis

Scrutinizes the statistics — appropriateness of tests, multiple-comparison handling, confidence intervals, model assumptions, and the reproducibility of the analyses.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_statistical_analysis.md

The manuscript “Code as Agent Harness” is a comprehensive survey that organizes a vast landscape of agentic systems. However, from a statistical analysis perspective, the paper relies heavily on point estimates and qualitative comparisons without the necessary statistical scaffolding to support rigorous scientific claims.

The primary concern is the reporting of performance metrics. Throughout the text, specific numerical claims are made regarding the efficacy of various systems (e.g., LingmaAgent resolving 16.9% of issues autonomously in §5.1; AIDE achieving 16.9% bronze medal rate in §5.1; QualityFlow’s Imagined Execution achieving 98%+ precision in §4.2). In the absence of experimental data generated by the authors, the survey must explicitly contextualize these numbers. For each cited metric, the manuscript should specify:

1. **Sample Size (N):** How many tasks, issues, or episodes were evaluated? A 16.9% success rate on 10 tasks is statistically distinct from the same rate on 1,000 tasks.
2. **Variance and Confidence:** Are these point estimates from a single run, or are they means with standard deviations or confidence intervals? The text currently presents these as fixed facts, ignoring the stochastic nature of LLM-based agents.
3. **Statistical Significance:** When comparing systems (e.g., “AIDE achieves roughly three times the medal rate of the next agent”), the text implies a significant difference. Without reported p-values or effect sizes, such comparative claims are descriptive rather than inferential.

Specifically, in Section 4.2, the claim of “98%+ precision” for Imagined Execution is a strong statistical assertion. The review requires the authors to cite the specific benchmark size and the ground-truth methodology used to derive this figure. Similarly, in Section 5.1, the aggregation of failure attribution accuracies into a “14–53% range” combines results from different studies (cemri2025whymas, zhang2025whoandwhen, etc.). The authors must clarify if these studies used comparable evaluation protocols and sample sizes, or if the range reflects heterogeneity in experimental design rather than a unified statistical distribution.

Finally, the discussion of “oracle adequacy” in Section 6.1 highlights the difficulty of evaluation but does not propose a statistical framework for it. The paper would benefit from a brief discussion on how future evaluations should report uncertainty (e.g., bootstrapped confidence intervals for pass rates) to distinguish between genuine system improvements and random variance. Until these statistical details are clarified or the claims are qualified as “reported point estimates,” the quantitative rigor of the survey remains insufficient for a definitive scientific assessment.

Action items.

- **[science]** The manuscript cites specific performance metrics (e.g., LingmaAgent 16.9%/43.3% in §5.1, AIDE 16.9% bronze in §5.1, 98%+ precision for Imagined Execution in §4.2) without providing confidence intervals, sample sizes (N), or statistical significance tests. As a survey, it must clarify if these are point estimates from single runs or aggregated results with variance.
- **[science]** Section 4.2 claims ‘98%+ precision’ for QualityFlow’s Imagined Execution. The review requires the specific dataset size, the definition of the ground truth used for this calculation, and whether this figure represents a mean over multiple seeds or a single experimental run to assess reproducibility.
- **[science]** In §5.1, the claim that ‘best step-level attribution accuracies’ are in the ‘14–53% range’ aggregates results from multiple studies (cemri2025whymas, zhang2025whoandwhen, etc.). The text should explicitly state the sample sizes and experimental conditions for each cited study to ensure the range is statistically comparable across different benchmarks.

Writing Quality

Reads the manuscript purely as prose — clarity, flow, sentence-level grammar, paragraph cohesion, and overall readability — setting the scientific content aside.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_writing_quality.md

The manuscript presents a comprehensive survey on “Code as Agent Harness,” but the writing quality is currently compromised by significant structural and editorial issues that impede readability. The most critical issue is the apparent duplication of major sections. Section 3 (“Harness Mechanisms”) and Section 4 (“Scaling the Harness”) appear to be repeated in the source material (comparing chunks e000/e001 with e004/e005), often with slightly different table contents or figure captions. This fragmentation suggests the document is a draft compilation rather than a finalized manuscript. A reader cannot follow the logical progression of the argument

when core definitions and taxonomies are presented in conflicting or redundant blocks.

Furthermore, the text contains numerous placeholders indicating incomplete data, such as “(... N rows omitted ...)” within tables (e.g., Table 2 in chunk e001, Table 4 in chunk e005). While this may be an artifact of the ingestion process, in a final paper, these tables must be fully populated or explicitly noted as “representative examples” to avoid confusing the reader about the scope of the survey. The inconsistency in citation commands (`\cite` vs. `\citep`) is also distracting and should be standardized to match the target venue’s style guide.

Finally, the “Open Problems” section is fragmented across multiple chunks with disjointed subheadings, breaking the flow of the concluding argument. The authors should consolidate these sections into a single, cohesive narrative. Once these structural duplications are resolved, the tables are completed, and the citation style is unified, the prose itself is generally clear and technically precise. However, as it stands, the document requires a full revision to ensure a coherent and professional presentation.

Action items.

- **[writing]** The manuscript contains significant structural duplication. Section 3 (‘Harness Mechanisms’) and Section 4 (‘Scaling the Harness’) appear twice in the source (e.g., e000 vs e004/e005), with conflicting table definitions and figure references. This must be consolidated into a single, linear narrative flow before publication.
- **[writing]** Several tables are truncated in the source with ‘(... N rows omitted ...)’ or ‘(... 10 rows omitted ...)’ placeholders (e.g., Table 2 in e001, Table 4 in e005). These must be fully expanded or the text must explicitly state that the table is illustrative, as incomplete tables disrupt readability and data integrity.
- **[writing]** Inconsistent citation formatting exists between `\cite{}` and `\citep{}` commands throughout the text (e.g., Section 5.1.1 uses `\citep` while Section 5.1.2 uses `\cite`). Standardize to the target venue’s required style (likely `\citep` for parenthetical) to ensure professional consistency.
- **[writing]** The ‘Open Problems’ section (Section 5.2) is split across multiple chunks (e002, e003, e004) with disjointed subheadings. Ensure the final compilation presents a unified, logically ordered list of open problems without redundant introductions or broken transitions.
