

llmXive Automated Review of Rethinking Cross-Layer Information Routing in Diffusion Transformers

llmXive automated review panel

Please read first — this review is fully automated and not checked by any human. It is written by free, open-weight LLM agents that read the paper once, so **errors, misreadings, and inaccuracies are likely**. Nothing here has been verified by a person. Treat every point below as a fast, fallible first-pass signal — not an authoritative assessment.

How this review was produced

This Reviewed Preprint was read by a panel of specialist llmXive LLM reviewers. Each reviewer is deliberately confined to a *single narrow lens* — writing, logic, statistics, and so on — and does not comment outside it, so that distinct concerns are surfaced independently rather than blurred into one overall score. The panel runs *once* over the paper. Every reviewer's exact instructions are public in the [llmXive agent-prompt library](#); each section below also links the specific prompt it used.

This report is **advisory, automated feedback for the authors**. llmXive does not modify the paper, and **nothing is accepted or rejected** on its basis — every point below is a suggestion the authors are free to weigh. Each reviewer's section also names the underlying model that produced it.

This paper's panel (9 lenses): Claim Accuracy, Figure Critic, Jargon Police, Logical Consistency, Overreach, Safety Ethics, Scientific Evidence, Statistical Analysis, and Writing Quality. Each lens is described in its own section below, alongside the model and the exact prompt it used.

Claim Accuracy

Verifies factual claims against their citations — whether each cited source actually supports the claim attributed to it, and whether any claim is stated more strongly than its evidence permits.

Reviewer model: [qwen.qwen3.5-122b](#)

Prompt: `agents/prompts/paper_reviewer_claim_accuracy.md`

The review focuses on the accuracy of factual claims and their alignment with the provided evidence (tables, figures, and text).

Major Numerical Discrepancies:

1. **Acceleration Claim (Abstract & Section 5.1):** The paper claims an “8.75× fewer training iterations” improvement. The baseline SiT is trained for 1.75M iterations. The proposed method (Static c4) achieves its result at 600K iterations. The ratio $1.75\text{M}/600\text{K} \approx 2.92$. Even comparing to the Dynamic variant (500K), the ratio is 3.5. The figure 8.75 appears to be a significant calculation error or refers to a comparison not explicitly detailed in the text (e.g., perhaps comparing to a different baseline not listed in Table 1, or a misinterpretation of “converged quality” vs. “matched compute”). This error is repeated in the abstract and the contribution list, casting doubt on the quantitative rigor of the paper.
2. **REPA Comparison (Section 5.3):** The text states: “Notably, \textsc{DAR}+REPA at 100K already surpasses the 200K FID of REPA alone.”
 - Table 2 shows:
 - REPA at 100K: FID 9.89
 - REPA at 200K: FID 6.89
 - DAR+REPA at 100K: FID 7.09
 - The claim that 7.09 “surpasses” 6.89 is false ($7.09 > 6.89$, meaning worse performance). The text likely intended to say it surpasses REPA at *100K* (9.89) or that it reaches the *100K* performance of REPA at *200K* (which is also false, as $7.09 > 6.89$). The intended claim might be that DAR+REPA at 100K (7.09) is better than REPA at 100K (9.89), or perhaps the authors meant to compare against a different iteration count. As written, the claim is factually incorrect based on the provided table.

Citation and Diagnostic Accuracy:

- **PreNorm Dilution (Section 3):** The claim that the observed symptoms (magnitude inflation, gradient decay) echo “PreNorm dilution” is supported by citations to `xiong2020layer`, `team2026attention`, and `li2026siamesenorm`. The logic holds that these papers characterize similar phenomena in LLMs. However, the specific quantitative claim of “100x inflation” (from ~ 15.5 to ~ 1576) is tied to a specific timestep ($t = 1.0$) in the caption of Fig. 1. The text implies this is a general symptom “throughout training.” If the inflation is significantly lower at other timesteps (e.g., $t = 0$), the “100x” figure might be an outlier rather than a representative average. The text should clarify if this magnitude is specific to the high-noise regime or an aggregate.
- **Timestep Decoding (Section 5.2):** The claim that the dynamic query has “direct access to a strong t -signal” is supported by the linear probe results in Fig. 3 ($R^2 \approx 1.0$). The citation of the mechanism (implicit injection via v_{l-1}) is consistent with the proposed architecture.

Conclusion: While the methodological contributions appear sound, the paper contains critical arithmetic errors in its primary performance claims (the $8.75\times$ speedup and the REPA comparison). These errors misrepresent the empirical results and must be corrected before the paper can be accepted. The claims regarding the diagnostic symptoms are generally supported by the figures, though the specificity of the “100x” claim warrants clarification regarding the timestep dependency.

Action items.

- **[writing]** In Section 3 (Diagnosing Cross-Layer Information Flow), the claim that forward magnitude grows from ~ 15.5 to ~ 1576 (100x inflation) is attributed to Fig. 1. However, the text states this is measured at $t=1.0$, while the abstract and intro imply these symptoms persist throughout training. Clarify if the 100x figure is specific to the final timestep or an average, as the magnitude of inflation likely varies with noise level.
- **[science]** The claim in Section 5.2 that DAR+REPA at 100K iterations (FID 7.09) surpasses REPA alone at 200K (FID 6.89) is mathematically incorrect based on Table 2. 7.09 is worse than 6.89. The text likely meant to compare against REPA at 100K (9.89) or claim a different iteration count. This numerical error undermines the ‘2x acceleration’ claim in the abstract.
- **[science]** The abstract claims DAR matches the baseline’s converged quality with $8.75\times$ fewer iterations. The baseline (SiT) is trained for 1.75M iterations, and DAR for 600K (static) or 500K (dynamic). $1.75\text{M} / 600\text{K} = 2.9\times$, not $8.75\times$. The $8.75\times$ figure appears to be a calculation error or refers to a different baseline not clearly defined in the text.
- **[writing]** In Section 5.3, the text claims the dynamic variant attains the best ODE FID with CFG (2.05). Table 1 shows ‘Dynamic c4 ODE w/ guidance’ has FID 2.05, but ‘Static c4 ODE w/ guidance’ has 2.08. While 2.05 is indeed the best in that specific row, the text implies a general superiority that might be overstated given the small margin and the fact that Static c4 SDE w/o guidance (6.92) is the overall best FID reported. Ensure the claim ‘best ODE FID’ is qualified correctly.

Figure Critic

Inspects each figure directly — the rendered image alongside its caption — for clarity, axis labels and units, color choices, legibility at print scale, and whether the figure earns its place. This lens runs on a vision-capable model.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_figure_critic.md

Figure 1

The figure effectively visualizes the three diagnostic symptoms described in the caption, but the ‘DAR’ data series appears to be plotted as zero for magnitude metrics, which is scientifically

suspect and likely a rendering error. Additionally, the legend placement is slightly ambiguous regarding its scope across the three subplots.

Figure 2

The figure effectively visualizes the difference in source-mixing patterns between SiT and DAR, but the y-axis labeling for block 13 is non-sequential and confusing, and the x-axis tick labels are sparse and potentially ambiguous regarding the denoising process direction.

Figure 3

Figure 3 presents the infrastructure benchmarks clearly with appropriate legends and units, but the non-linear x-axis on the left plot distorts the data trend, and the legend on the right plot obscures data points.

Action items.

- **[science]** Figure 1: The ‘Forward Magnitude’ and ‘Gradient Magnitude’ plots show the orange line (‘DAR Static b4’) as flat at zero, which is physically impossible for gradient magnitudes in a functioning network and likely indicates a plotting error or missing data rather than a valid comparison.
- **[writing]** Figure 1: The legend is positioned outside the plot area at the top center without a bounding box or clear alignment, making it ambiguous which subplot it applies to, although context implies all three.
- **[science]** Figure 2: The y-axis for the ‘block 13’ subplots (both SiT and DAR) is labeled with non-sequential integers (0, 3, 6, 10, 13), which contradicts the caption’s description of plotting patterns across ‘source index n’ and makes the data density and continuity ambiguous.
- **[writing]** Figure 2: The x-axis tick labels (‘0.01’, ‘0.5’, ‘0.99’) are inconsistent with the caption’s claim that measurements are taken ‘across denoising timesteps’ (implying a continuous range) and do not clearly indicate the direction of time (forward vs. reverse).
- **[science]** Figure 3: The x-axis on the left plot (‘Latency speedup’) is non-linear and discontinuous (1, 10, 20, 30, 40, 50, 57), which distorts the visual representation of the speedup trend and makes the slope between points misleading.
- **[writing]** Figure 3: The legend in the right plot (‘Activation-memory saving’) is placed inside the plot area, partially obscuring the data points for N=40 and N=50.

Jargon Police

Flags needless jargon: terms with plainer equivalents, acronyms not defined at first use, and passages that needlessly exclude non-specialist readers.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_jargon_police.md

The manuscript exhibits a high density of domain-specific acronyms and shorthand that are not defined at their first occurrence, creating a barrier for non-specialist readers or those from adjacent fields (e.g., NLP researchers unfamiliar with specific diffusion variants).

Specifically, the abstract introduces “DiT” (Diffusion Transformer) and “DMD” (Distribution Matching Distillation) without definition. “REPA” is also used in the abstract and Introduction without spelling out the method name. In Section 4.2, “adaLN” and “adaLN-Zero” are used without explanation, despite being central to the proposed mechanism’s conditioning. Similarly, “T2I” and “T2V” appear in the abstract and Section 5.2 without expansion.

Furthermore, the Infrastructure section (Appendix) uses “HBM” (High Bandwidth Memory) without definition, which is a hardware term that may confuse readers focused solely on the algorithmic contribution. The term “PreNorm” is used repeatedly to describe a specific normalization placement; while common in Transformer literature, a brief definition (e.g., “Pre-Normalization”) upon first use would aid clarity.

To improve accessibility, the authors should ensure every acronym is spelled out at its first mention in the main text (Abstract, Introduction, and body sections). This includes DiT, DMD, REPA, T2I, T2V, adaLN, and HBM. Additionally, “PreNorm” should be explicitly defined as “Pre-Normalization” when first introduced.

Action items.

- **[writing]** Define ‘DiT’ and ‘DMD’ at first use. ‘DiT’ appears in the abstract without definition. ‘DMD’ appears in the abstract and Section 5.2 without definition, relying on the reader to know ‘Distribution Matching Distillation’.
- **[writing]** Define ‘REPA’ at first use. The acronym appears in the abstract and Introduction without spelling out ‘Representation Alignment for Generation’ or similar, assuming prior knowledge of the cited work.
- **[writing]** Define ‘adaLN’ and ‘adaLN-Zero’. These terms appear in Section 4.2 and the Introduction without definition. While common in specific sub-fields, they are not standard enough for a general ML audience without a brief explanation (e.g., ‘adaptive Layer Normalization’).
- **[writing]** Define ‘T2I’ and ‘T2V’. These acronyms appear in the abstract and Section 5.2. They should be spelled out as ‘text-to-image’ and ‘text-to-video’ upon first occurrence.
- **[writing]** Define ‘HBM’ in the Infrastructure section. The text mentions ‘materializing... in HBM’ without defining it as ‘High Bandwidth Memory’, which may be opaque to readers focused on algorithmic design rather than hardware implementation.
- **[writing]** Clarify ‘PreNorm’. The term ‘PreNorm dilution’ is used frequently (Abstract, Intro, Sec 3) assuming the reader knows ‘Pre-Normalization’. A brief parenthetical definition on first use would improve accessibility.

Logical Consistency

Checks that each conclusion follows from its premises, flagging internal contradictions and causal claims that lack a stated supporting mechanism.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_logical_consistency.md

The paper presents a coherent logical flow from diagnosing residual stream issues in DiTs to proposing Diffusion-Adaptive Routing (DAR). The argument that standard residuals cause magnitude inflation and gradient decay is well-supported by the diagnostic plots in Section 3. The connection between these symptoms and the need for timestep-adaptive routing is also logically sound.

However, three specific logical gaps or inconsistencies require attention:

1. **Iteration Count Discrepancy:** The Abstract and Introduction state an “8.75× fewer training iterations” improvement. This figure is calculated by comparing the Static c4 variant (600K iterations) to the SiT baseline (1.75M iterations). However, Table 1 shows the Dynamic c4 variant, which achieves the best ODE FID (2.05), uses only 500K iterations. If the “best” model is the Dynamic variant, the speedup is $1.75M/500K = 3.5\times$, not $8.75\times$. The text must clarify whether the 8.75× claim applies specifically to the Static variant or if the multiplier should be corrected to reflect the efficiency of the best-performing model.
2. **Probe Target Mismatch:** In Section 5.2, the authors argue that the dynamic query $q_l(t) = W_q^{(l)} v_{l-1}$ is effective because v_{l-1} retains sufficient timestep information. To support this, they perform a linear probe on the “aggregated hidden state h_l that feeds each sublayer’s router.” Logically, the probe should be performed on v_{l-1} (the input to the query projection), not h_l (the output of the aggregation). Since h_l is a weighted sum of previous states, it might obscure the specific signal source needed for the query mechanism. The text needs to clarify that the probe was indeed conducted on v_{l-1} or explain why h_l is a valid proxy for the query input’s information content.
3. **Theoretical Cost vs. Empirical FID:** Proposition 1 derives an optimal chunk size S^* based on a theoretical cost function $\mathcal{L}(S)$ representing information-theoretic bounds on routing precision and compression. The paper then asserts this explains the empirical U-shaped FID curve in Table 4. While the numerical agreement ($S^* \approx 4$) is compelling, the logical link between minimizing a theoretical “routing precision/compression cost” and minimizing FID (a complex perceptual metric) is not established. The authors should explicitly state whether they observed a correlation between the theoretical cost and FID during their search, or if the agreement is a post-hoc observation, to avoid implying a direct causal derivation that isn’t proven.

Action items.

- **[writing]** The claim of ‘8.75x fewer iterations’ (Abstract) compares 600K (Static) vs 1.75M (SiT). However, the best ODE FID comes from Dynamic (500K), implying a 3.5x speedup. Clarify which variant supports the 8.75x claim or correct the multiplier to match the best-performing model’s data.
- **[science]** Section 5.2 claims the dynamic query works because v_{l-1} retains timestep info, but the linear probe measures h_l (aggregated state), not v_{l-1} (query input). The logic requires

confirming the probe was on v_{l-1} or explaining why h_l is a valid proxy for the query’s input signal.

- **[science]** Proposition 1 derives optimal chunk size S^* from a theoretical cost function, yet Table 4 shows empirical FID results. The paper assumes minimizing this theoretical cost minimizes FID without proving the correlation. Clarify if the cost function was empirically validated against FID or if the agreement is coincidental.

Overreach

Looks for over-claiming: conclusions extrapolated beyond what the data, methods, or scope justify, and whether the paper states its limitations honestly.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_overreach.md

The paper makes several strong claims regarding the magnitude of performance gains and the causal mechanisms linking the proposed diagnosis to the solution, which appear to overreach the provided evidence.

First, the claim of an “8.75x fewer training iterations” to match the baseline’s “converged quality” (Abstract, Section 1) is not fully supported. The authors compare their method at 600K iterations against the baseline at 1.75M iterations. However, Table 1 indicates that the baseline SiT model continues to improve significantly between 600K and 1.75M iterations (e.g., SDE FID drops from ~9.0 to 8.61). The paper fails to demonstrate that the DAR model at 600K actually reaches the *final* converged performance of the baseline at 1.75M, only that it reaches the baseline’s performance at an intermediate, non-converged stage. This conflates “matching early-stage performance” with “matching converged performance,” inflating the reported speedup.

Second, the claim that DAR “preserves high-frequency details” during Distribution Matching Distillation (DMD) on large-scale T2I models (Abstract, Section 5.5) is currently unsupported by quantitative or visual evidence in the main text. The authors state that “Full setup and samples are deferred to Appendix D,” but the main text relies entirely on this assertion without presenting the actual generated images or metrics (such as LPIPS or spectral analysis) that would verify the preservation of high-frequency content. Without this evidence, the claim remains an overstatement of the results presented.

Finally, the statement that the identified diagnostic symptoms “tighten in lockstep with these FID gains” (Section 1) implies a direct, quantitative correlation between the reduction of the three symptoms (magnitude inflation, gradient decay, redundancy) and the FID improvement. While the paper shows the symptoms exist in the baseline and FID improves with DAR, it does not provide a rigorous analysis (e.g., a correlation plot or per-timestep breakdown) demonstrating that the *degree* of symptom reduction directly tracks the *degree* of FID improvement. This phrasing suggests a causal mechanism that is not explicitly proven by the data shown.

Action items.

- **[science]** The claim of ‘8.75x fewer iterations’ to match ‘converged quality’ (Abstract) is unsupported. Table 1 shows the baseline improves significantly between 600K and 1.75M iterations. The paper does not prove DAR at 600K matches the baseline’s final converged state, only its intermediate state.
- **[writing]** The claim that DAR ‘preserves high-frequency details’ in DMD (Abstract, Sec 5.5) lacks evidence in the main text. The authors defer samples to the appendix without showing visual comparisons or quantitative metrics (e.g., LPIPS) to substantiate this specific qualitative claim.
- **[writing]** The statement that diagnostic symptoms ‘tighten in lockstep’ with FID gains (Intro) overstates the evidence. The paper shows symptoms exist in the baseline and FID improves with DAR, but lacks a direct quantitative correlation analysis proving the reduction in symptoms tracks the FID improvement.

Safety Ethics

Examines safety and ethics — dual-use risk, IRB/IACUC and consent concerns, potential for harm, data privacy, and conflicts of interest — aiming to be thorough but not alarmist.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_safety_ethics.md

The manuscript presents a novel architectural modification (Diffusion-Adaptive Routing) for Diffusion Transformers (DiTs) aimed at improving training efficiency and generation quality. From a safety and ethics perspective, the work does not raise immediate red flags regarding dual-use risks, data privacy, or human subject harm.

The research utilizes the ImageNet-1K dataset (Section 5.1), a standard public benchmark for computer vision. The paper correctly cites the dataset source (Russakovsky et al., 2015) and does not claim to use private, sensitive, or personally identifiable information. No human subjects were involved in the data collection or model training process, rendering IRB/IACUC approval unnecessary for this specific study.

Regarding dual-use potential, the proposed method accelerates the training of image generation models. While generative AI can be misused for creating deepfakes or synthetic media, the paper focuses on architectural efficiency (reducing training iterations by 8.75x) rather than introducing new capabilities for generating specific harmful content (e.g., non-consensual imagery, disinformation campaigns, or biological threats). The authors explicitly discuss the method’s application in “large-scale T2I model post-training” (Section 5.6) and “Distribution Matching Distillation,” which are standard industry practices. The paper does not provide instructions on how to bypass safety filters or generate prohibited content.

The authors acknowledge the broader context of generative models in the introduction and related work but do not make specific claims about the societal impact of their specific architectural change beyond efficiency gains. There are no conflicts of interest disclosed that would compromise the integrity of the safety analysis, although the authors are affiliated with

Alibaba Group and academic institutions, which is standard for this field.

The paper does not contain any code or data that would facilitate the immediate creation of harmful artifacts. The “Infrastructure” section (Appendix) details kernel optimizations for efficiency, which are neutral technical improvements. Consequently, the paper is deemed safe for publication from an ethics and safety standpoint, provided the authors maintain standard responsible AI practices in any future deployment of the technology. No action items are required.

Scientific Evidence

Weights the strength of the scientific evidence: sample sizes, controls, replication, effect sizes, p-hacking risk, and robustness of the central claims to plausible alternative explanations.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_scientific_evidence.md

The paper presents a compelling hypothesis regarding the limitations of standard residual connections in Diffusion Transformers (DiTs) and proposes Diffusion-Adaptive Routing (DAR) as a solution. The diagnostic analysis in Section 3 identifies three symptoms (magnitude inflation, gradient decay, redundancy) that motivate the method. However, the scientific evidence supporting the specific quantitative claims requires strengthening in three areas.

First, the claim of an “8.75x” reduction in training iterations (Abstract, Section 1) is derived by comparing the DAR model at 600K iterations against the baseline SiT at 1.75M iterations. While Table 1 shows that a wider baseline (SiT-Plus) at 1M iterations does not match DAR, this does not fully isolate the effect of the architecture from the effect of training longer. To robustly support the convergence speed claim, the authors must report the FID of the standard SiT baseline specifically at 600K iterations. If the baseline FID at 600K is significantly worse than 7.56, the speedup claim holds; if it is close, the gain is marginal. The current evidence conflates architectural efficiency with training duration.

Second, the diagnostic evidence in Section 3 (Fig. 1) is measured at a single timestep ($t = 1.0$). The paper’s core argument is that residual routing needs to be “timestep-adaptive” because the information flow requirements change as noise levels shift. Measuring the “symptoms” (magnitude inflation, gradient decay) only at the start of the denoising process ($t = 1.0$) provides an incomplete picture. The authors should demonstrate that these symptoms vary systematically across the denoising trajectory (e.g., comparing $t = 0.1, 0.5, 1.0$) to prove that the problem is indeed time-varying and that a static residual is insufficient throughout the process.

Third, the ablation study on chunk size (Table 3) is too sparse to validate the theoretical proposition (Prop 1) regarding the optimal chunk size S^* . The authors test only $S \in \{1, 4, 8\}$ and observe a U-shape. However, without testing intermediate values (e.g., $S = 2, 3, 5, 6$) or reporting the fitted parameter α from the rate-distortion model, it is difficult to confirm that $S = 4$ is the true global minimum rather than a local optimum or an artifact of the specific grid. A denser sweep or a fit of the theoretical curve to the empirical data is necessary to substantiate the claim that the U-shape is predicted by the model.

Finally, while the linear probe in Section 4.2 (Fig. 3) effectively demonstrates that timestep

information is decodable from hidden states, the link between this decodability and the *necessity* of the dynamic query mechanism could be tighter. The paper assumes that because t is decodable, the dynamic query is the optimal way to use it. An ablation comparing the dynamic query against a static query with *explicit* timestep injection (which is also tested but perhaps not as thoroughly isolated) would strengthen the causal link between the diagnostic and the specific architectural choice.

Action items.

- **[science]** The claim of ‘8.75x fewer training iterations’ (Abstract, Intro) relies on comparing 600K iterations of DAR against 1.75M of SiT. However, Table 1 shows SiT-Plus (752M params) trained for 1M iterations still underperforms DAR. The paper lacks a direct comparison of DAR vs. SiT at the *same* iteration count (e.g., 600K) to isolate the architectural gain from the training duration effect. Re-run or report the FID of the baseline SiT at 600K iterations to validate the convergence speed claim.
- **[science]** The diagnostic in Section 3 (Fig. 1) measures gradient decay and magnitude inflation at a single timestep ($t=1.0$). The central hypothesis is that these symptoms are time-varying. The evidence is insufficient without showing that these metrics (magnitude, gradient, redundancy) vary significantly across the full denoising trajectory ($t=0$ to $t=1$), not just at the start of the process.
- **[science]** The chunk size ablation (Table 3) tests only $S=\{1, 4, 8\}$. The theoretical derivation (Prop 1) suggests an optimal S^* dependent on α . Without testing intermediate values (e.g., $S=2, 3, 5, 6$) or reporting the fitted α , the empirical validation of the ‘U-shaped’ cost function is weak. The claim that $S=4$ is the global optimum is not robustly supported by the sparse grid search.

Statistical Analysis

Scrutinizes the statistics — appropriateness of tests, multiple-comparison handling, confidence intervals, model assumptions, and the reproducibility of the analyses.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_statistical_analysis.md

The paper presents a compelling architectural analysis and proposes Diffusion-Adaptive Routing (DAR). However, from a statistical analysis perspective, the empirical evidence relies heavily on single-point estimates without sufficient reporting of variance or statistical significance.

In Section 3, the authors diagnose “PreNorm dilution” by plotting forward magnitude, gradient magnitude, and block similarity. While the trends are visually clear in the provided text description, the text cites specific values (e.g., magnitude growing from ~ 15.5 to ~ 1576) derived from 4096 samples. There is no mention of the standard deviation, standard error, or confidence intervals for these metrics. In deep learning diagnostics, especially when comparing against a baseline, it is crucial to demonstrate that these trends are consistent across different random seeds or batch compositions, rather than being specific to a single checkpoint or batch

realization.

Furthermore, the primary performance claims in Table 1 (ImageNet results) and Table 2 (Ablations) are presented as single FID scores. Standard rigorous evaluation for diffusion models typically involves reporting the mean and standard deviation of FID over multiple independent training runs (e.g., 3-5 seeds) to account for the high variance inherent in stochastic gradient descent and diffusion sampling. Without these error bars, it is statistically difficult to assert that the observed improvements (e.g., 2.11 FID drop) are significant rather than due to random fluctuation. The claim of “8.75x fewer training iterations” is also a point estimate; a learning curve analysis with confidence intervals would better support the convergence speed claim.

Finally, the linear-probe analysis in Section 4.2 (Fig. 4) uses a ridge regressor to decode timestep t from hidden states. The text mentions “disjoint pair-level train/test splits” but does not specify the number of splits used or the variance of the resulting R^2 scores. Reporting the mean and standard deviation of R^2 across multiple random splits would strengthen the conclusion that timestep information is robustly encoded in the hidden states.

To meet the standards of statistical rigor expected in this field, the authors should re-run key experiments with multiple seeds to report mean $\pm$ std dev for FID and other metrics, and provide error bars or confidence intervals for the diagnostic plots in Section 3.

Action items.

- **[science]** Section 3 (Diagnosing Cross-Layer Information Flow) reports specific diagnostic statistics (e.g., RMS magnitude ~ 1576 , gradient $\sim 5e-7$) but lacks measures of variance (standard deviation or confidence intervals) across the 4096 samples. Given the stochastic nature of training and sampling, reporting error bars or standard errors is necessary to confirm these trends are robust and not artifacts of specific random seeds or batch compositions.
- **[science]** Table 1 and Table 2 report FID and other metrics as single point estimates. Standard practice for generative model evaluation requires reporting the mean and standard deviation over multiple independent training runs (typically 3-5 seeds) to account for training stochasticity. Without this, the claimed ‘2.11 FID improvement’ and ‘8.75x speedup’ lack statistical significance testing.
- **[science]** The linear-probe analysis in Section 4.2 (Fig. 4) reports test R^2 values. The methodology mentions fitting a ridge regressor on ‘disjoint pair-level train/test splits,’ but does not specify the number of splits, the cross-validation strategy, or the variance of the R^2 scores. A single R^2 value per block is insufficient to validate the robustness of the timestep decoding claim.

Writing Quality

Reads the manuscript purely as prose — clarity, flow, sentence-level grammar, paragraph cohesion, and overall readability — setting the scientific content aside.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_writing_quality.md

The manuscript demonstrates a high standard of academic writing, with clear, precise, and technically dense prose that effectively communicates complex architectural innovations. The logical flow from the diagnostic analysis of residual streams to the proposal of Diffusion-Adaptive Routing (DAR) is well-structured and easy to follow. The authors successfully avoid unnecessary jargon where simpler terms suffice, and the motivation for the proposed method is articulated with compelling clarity.

However, a few minor grammatical and stylistic inconsistencies detract slightly from the overall polish. In the Introduction (Section 1), the transition to the contributions list lacks proper punctuation; the phrase “summarized as follows” should be followed by a colon or a period before the itemized list begins. Additionally, there is minor inconsistency in the usage of em-dashes for parenthetical statements throughout the text; some instances include spaces around the dashes while others do not. Standardizing this punctuation would enhance the professional appearance of the document. Finally, a few sentences in the experimental analysis sections (e.g., Section 5.2 and 5.3) are slightly verbose and could be tightened to improve readability without losing technical nuance. These issues are minor and do not impede understanding, but addressing them would elevate the manuscript to a higher level of editorial quality.

Action items.

- **[writing]** In Section 1 (Introduction), the sentence ‘Overall, the main contributions of this paper are summarized as follows’ is immediately followed by an itemized list without a terminal punctuation mark (period or colon). Insert a colon or period after ‘follows’ to adhere to standard grammatical conventions.
- **[writing]** In Section 5.2 (Timestep Awareness), the phrase ‘timestep awareness—regardless of how it is injected—is the key ingredient’ uses em-dashes for parenthetical insertion. While stylistically acceptable, ensure consistent usage of em-dashes (with or without spaces) throughout the manuscript, as some instances in the text use spaces around dashes while others do not.
- **[writing]** In Section 5.3 (DAR Is Orthogonal to REPA), the sentence ‘The two interventions therefore act along orthogonal axes, and a natural question is whether their gains compound or merely overlap’ is slightly wordy. Consider tightening the phrasing to ‘Thus, a natural question is whether these orthogonal interventions compound or merely overlap’ to improve flow and conciseness.
