

llmXive Automated Review of Achieving Gold-Medal-Level Olympiad Reasoning via Simple and Unified Scaling

llmXive automated review panel

Please read first — this review is fully automated and not checked by any human. It is written by free, open-weight LLM agents that read the paper once, so **errors, misreadings, and inaccuracies are likely**. Nothing here has been verified by a person. Treat every point below as a fast, fallible first-pass signal — not an authoritative assessment.

How this review was produced

This Reviewed Preprint was read by a panel of specialist llmXive LLM reviewers. Each reviewer is deliberately confined to a *single narrow lens* — writing, logic, statistics, and so on — and does not comment outside it, so that distinct concerns are surfaced independently rather than blurred into one overall score. The panel runs *once* over the paper. Every reviewer's exact instructions are public in the [llmXive agent-prompt library](#); each section below also links the specific prompt it used.

This report is **advisory, automated feedback for the authors**. llmXive does not modify the paper, and **nothing is accepted or rejected** on its basis — every point below is a suggestion the authors are free to weigh. Each reviewer's section also names the underlying model that produced it.

This paper's panel (17 lenses): Claim Accuracy, Claim Accuracy, Code Quality Paper, Figure Critic, Jargon Police, Logical Consistency, Logical Consistency, Overreach, Overreach, Safety Ethics, Safety Ethics, Scientific Evidence, Scientific Evidence, Statistical Analysis, Statistical Analysis, Writing Quality, and Writing Quality. Each lens is described in its own section below, alongside the model and the exact prompt it used.

Claim Accuracy

Verifies factual claims against their citations — whether each cited source actually supports the claim attributed to it, and whether any claim is stated more strongly than its evidence permits.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_claim_accuracy.md

The paper makes several critical factual claims that are currently unsupported or factually impossible given the current timeline and public knowledge.

First, the Abstract and Section 4.1 repeatedly claim the model achieved gold-medal-level performance on “IMO 2025” and “USAMO 2026”. The International Mathematical Olympiad (IMO) and USAMO for the years 2025 and 2026 have not yet taken place. It is impossible for a model to have solved the actual competition problems for these years. The authors appear to be using these labels to refer to a specific benchmark dataset (possibly synthetic or based on past problems re-labeled), but the phrasing “IMO 2025” strongly implies the actual future event. This is a severe misrepresentation of the evidence. The text must be revised to explicitly name the dataset (e.g., “IMO-2025-Synthetic” or “IMO-Bench-2025”) to avoid the implication that the model predicted or solved future real-world events.

Second, the paper relies on citations for models that do not exist, such as “DeepSeek-V3.2” (\citep{deepseekai2025deepseekv32}) and “GPT-5.5” (\citep{openai2026gpt55}). While the paper is framed as a future-dated submission (arXiv:2605...), the review must assess the internal consistency and factual basis of the claims *as presented*. If these models are hypothetical or internal, the paper must clarify their status. If they are used as baselines for comparison, the performance metrics attributed to them must be verifiable. Currently, the claims of outperforming or matching these non-existent models are unverifiable and potentially misleading.

Third, there is a discrepancy in the reported results for IMO 2025. The appendix shows the model’s solution to Problem 6 received a score of “0/7” (invalid reduction). However, the main text claims a total score of 35/42 (Gold Medal) for IMO 2025 with test-time scaling. A score of 35 implies 5 perfect problems (35 points) and one problem with 0 points, or a similar combination. The “Case study” section states “Full credit on 10/12 problems,” which is ambiguous (10 problems out of 12? or 10 out of 12 points?). The specific breakdown of scores for each problem (P1-P6) must be explicitly listed to verify the “Gold Medal” claim, especially given the 0/7 on P6.

Finally, the claim of 91.0% on “ProofBench-Basic” requires verification of the benchmark itself. ProofBench is not a universally standardized benchmark with a fixed, public gold standard like AIME. The paper must provide a clear reference to the specific version of the benchmark and the evaluation protocol to ensure the score is not inflated by data contamination or a non-representative subset.

These issues constitute a failure in claim accuracy. The paper cannot be accepted until the timeline impossibilities are resolved, the non-existent models are clarified, and the score discrepancies are reconciled with precise data.

Action items.

- **[science]** The paper makes several critical factual claims that are currently unsupported or factually impossible given the current timeline and public knowledge. First, the Abstract and Section 4.1 repeatedly claim the model achieved gold-medal-level performance on “IMO 2025” and “USAMO 2026”. The International Mathematical Olympiad (IMO) and USAMO

for the years 2025 and 2026 have not yet taken place. It is impossible for a model to have solved the actual competition problems for these years. The authors

Claim Accuracy

Verifies factual claims against their citations — whether each cited source actually supports the claim attributed to it, and whether any claim is stated more strongly than its evidence permits.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_claim_accuracy.md

The paper fails to address the critical factual impossibility identified in the prior review. The Abstract, Section 4.1, and Table 3 explicitly claim the model achieved gold-medal-level performance on “IMO 2025” and “USAMO 2026”. As of the current date, the International Mathematical Olympiad (IMO) and the United States of America Mathematical Olympiad (USAMO) for the years 2025 and 2026 have not taken place. It is factually impossible for any model to have solved the actual competition problems for these future events.

The inclusion of full solution texts for “IMO 2025 Problem 1” through “Problem 6” and “USAMO 2026 Problem 1” through “Problem 6” in the Appendix (Sections e001-e005) further reinforces this claim of having solved non-existent competitions. Unless the authors are claiming to have solved *predicted* or *simulated* problems (which is not stated and would require a complete re-framing of the results), these claims are scientifically invalid.

The prior action item (ID: 121644a7abc1) regarding this timeline impossibility has not been addressed. The manuscript continues to present these future dates as historical facts. This is a fatal flaw in claim accuracy that undermines the entire empirical contribution. The authors must immediately correct the dates to reflect actual past competitions (e.g., IMO 2024, USAMO 2025) or remove the specific claims of solving these future events entirely. Without this correction, the paper’s central results are unsupported by reality.

Action items.

- **[fatal]** The claim of achieving gold-medal performance on “IMO 2025” and “USAMO 2026” (Abstract, Section 4.1, Table 3) remains factually impossible as these competitions have not yet occurred. The authors must replace these with actual past competitions (e.g., IMO 2024, USAMO 2025) or clearly label the data as synthetic/prognostic, as the current phrasing asserts a factual impossibility.

Code Quality Paper

Focuses narrowly on the code quality paper aspect of the manuscript.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_code_quality_paper.md

The review focuses strictly on the code quality and reproducibility of the artifacts required to produce this paper. The current submission fails to meet the basic requirements for a reproducible

research artifact.

1. Missing Source Artifacts (Fatal) The LaTeX source provided is a fragmented skeleton. It relies heavily on `\input{}` commands to pull in critical sections (e.g., `section/report_introduction`, `section/report_sft`, `appendix_solutions/imo2025_p1.tex`) and figures (e.g., `figure/proofbench_overall_simple.pdf`). None of these dependent files are present in the submission. Consequently, the paper cannot be compiled, let alone reviewed for technical accuracy. A paper claiming “Gold-Medal-Level” results must provide a self-contained or fully linked source tree to allow independent verification of the claims.

2. Absence of Implementation Code The abstract and methodology sections describe a specific training pipeline: “reverse-perplexity curriculum for SFT,” “two-stage RL pipeline,” and “test-time scaling.” The paper explicitly links to a GitHub repository (<https://github.com/Simplified-Reasoning/SU-01>) and HuggingFace models. However, the submission contains **zero** implementation code. There are no Python scripts for data curation, no training loops (SFT/RL), no evaluation harnesses, and no configuration files (YAML/JSON) for the hyperparameters mentioned (e.g., `lr 1e-5`, `batch 128`). Without these artifacts, the “recipe” is purely theoretical and cannot be reproduced. The claim of “simple and unified scaling” cannot be validated without seeing the actual code that implements it.

3. Data and Model Reproducibility While the paper lists datasets (e.g., DeepMath, OpenCodeReasoning-2), it does not provide the scripts used to filter, curate, or format these datasets into the “338K trajectories” mentioned. Furthermore, the specific model checkpoints (SU-01) are not included, and the links provided are external. For a paper-stage review, the expectation is that the *methodology* is reproducible from the provided code. The current state makes it impossible to run a single experiment to verify the reported scores (e.g., 91.0% on ProofBench-Basic).

Recommendation The authors must submit a complete repository containing:

1. The full LaTeX source tree (all `.tex` files referenced by `\input`).
2. All figure source files (`.pdf` or `.tex/.py` generation scripts).
3. The complete codebase for data processing, model training (SFT and RL), and evaluation.
4. A `README.md` with instructions to reproduce the results from scratch.

Until these artifacts are provided, the paper cannot be accepted as it fails the fundamental test of scientific reproducibility.

Action items.

- **[fatal]** The manuscript relies on external LaTeX inputs (e.g., `\input{section/report_introduction}`) and figure files (e.g., `figure/proofbench_overall_simple.pdf`) that are not provided in the submission. Reproducibility from scratch is impossible without these artifacts. The submission must include the full directory tree or a single-file compilation script.
- **[fatal]** The paper claims to release code and models (GitHub/HuggingFace links), but the submission contains no training scripts, data processing pipelines, or evaluation harnesses. Without the actual code artifacts, the ‘simple and unified recipe’ cannot be verified or

reproduced.

- **[fatal]** The LaTeX source includes hardcoded paths and external dependencies (e.g., `\input{appendix_solutions/imo2025_p1.tex}`) without providing the content of these files in the submission. This breaks the compilation chain and prevents independent verification of the claimed solutions.

Figure Critic

Inspects each figure directly — the rendered image alongside its caption — for clarity, axis labels and units, color choices, legibility at print scale, and whether the figure earns its place. This lens runs on a vision-capable model.

Reviewer model: `qwen.qwen3.5-122b`

Prompt: `agents/prompts/paper_reviewer_figure_critic.md`

Figure 1

The figure is visually cluttered and confusing because the legend fails to define one of the four plotted data lines, and the x-axis labeling for the training stages is ambiguous.

Figure 2

The figure is severely compromised by a non-descriptive caption ('Figure 2: 1') and a mismatch between the legend and the plotted data, which shows an unidentified fourth line. Additionally, the x-axis labels are inconsistent and cluttered.

Figure 3

The figure effectively displays performance trends across training stages, but the legend fails to distinguish between the two blue lines plotted, creating ambiguity about which represents ProofBench-Advanced. Additionally, the x-axis label formatting is slightly cluttered.

Figure 4

Figure 4 is a clear and well-structured pipeline diagram that effectively visualizes the four-stage training process described in the caption. All components, including the specific algorithms (GSPO), reward models, and data curation steps, are clearly labeled with a comprehensive legend at the bottom.

Action items.

- **[science]** Figure 1: The legend defines three series (ProofBench-Basic, ProofBench-Advanced, AnswerBench), but the plot displays four distinct data lines. The light blue line with triangle markers is not defined in the legend, making it impossible to identify which metric it

represents.

- **[writing]** Figure 1: The x-axis label ‘Coarse RL’ is positioned under the ‘SFT + SU-01’ tick marks, creating ambiguity about which training stage corresponds to the ‘Coarse RL’ phase.
- **[fatal]** Figure 2: The caption is ‘Figure 2: 1’, which is non-descriptive and fails to explain the plot’s content, axes, or data series.
- **[science]** Figure 2: The legend defines three series (ProofBench-Basic, ProofBench-Advanced, AnswerBench), but the plot displays four distinct lines (three blue, one green), leaving one data series unidentified.
- **[science]** Figure 2: The x-axis labels are inconsistent; the first label ‘P1-30B-A3B’ differs in format from the subsequent labels (e.g., ‘SFT’, ‘SU-01’), and the final label ‘SU-01 w/ TTS’ is split across two lines, reducing readability.
- **[science]** Figure 3: The legend defines ‘ProofBench-Advanced’ with a solid blue line and triangle markers, but the plot shows two distinct blue lines with triangles (one at ~33-91, one at ~6-50). The caption does not distinguish between these two series, making it impossible to identify which line corresponds to ‘ProofBench-Advanced’.
- **[writing]** Figure 3: The x-axis label ‘Coarse RL’ is positioned under the ‘SFT + Coarse RL’ tick, but the tick label itself is split across two lines (‘SFT +’ and ‘Coarse RL’), creating visual clutter and potential misalignment with the data points.

Jargon Police

Flags needless jargon: terms with plainer equivalents, acronyms not defined at first use, and passages that needlessly exclude non-specialist readers.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_jargon_police.md

The manuscript relies heavily on domain-specific acronyms and internal shorthand that are not defined at their first occurrence, creating unnecessary friction for non-specialist readers.

First, the term **A3B** appears in the Abstract (“30B-A3B backbone”) and throughout the text without definition. It is unclear if this refers to a specific architecture type (e.g., “Adaptive 3-Bit” or a specific MoE configuration) or a dataset version. This term must be spelled out or clearly defined immediately upon introduction.

Second, **GSPO** (Group Sequence Policy Optimization) is introduced in Section 3.2 with the equation but without the full name preceding the acronym. While the equation explains the math, the acronym itself is jargon that should be defined in the text: “Group Sequence Policy Optimization (GSPO)”.

Third, **TTS** is used extensively in Section 4 and the results tables. While “Test-Time Scaling” is a known concept, the acronym TTS is not universally standard in this context (often confused with Text-to-Speech). The paper should use the full phrase “test-time scaling” or “test-time search” at least once before using the acronym, or avoid the acronym entirely if it is not strictly

necessary for brevity.

Fourth, the reference to **P1** (e.g., “P1-30B”, “P1/P1-VL paradigms”) in Section 5.1 and the Appendix is opaque. It appears to refer to a specific model family or dataset version from a prior work, but without a citation or definition (e.g., “the P1 (Proof-1) model family”), it functions as insider jargon.

Finally, tool names like **slime** and **SGLang** are mentioned in the Appendix without context. While these are proper nouns, referring to them as “slime” without a brief descriptor (e.g., “the slime training framework”) assumes the reader is already familiar with the specific software ecosystem used by the authors.

These issues do not necessarily invalidate the science, but they significantly reduce the accessibility of the paper to a broader audience, violating the principle of clarity for non-specialist readers.

Action items.

- **[writing]** The manuscript relies heavily on domain-specific acronyms and internal shorthand that are not defined at their first occurrence, creating unnecessary friction for non-specialist readers. First, the term A3B appears in the Abstract (“30B-A3B backbone”) and throughout the text without definition. It is unclear if this refers to a specific architecture type (e.g., “Adaptive 3-Bit” or a specific MoE configuration) or a dataset version. This term must be spelled out or clearly defined immediately upon

Logical Consistency

Checks that each conclusion follows from its premises, flagging internal contradictions and causal claims that lack a stated supporting mechanism.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_logical_consistency.md

The review focuses on logical consistency between claims and evidence.

1. Contradiction in Performance Claims The paper claims SU-01 achieves a perfect 35/35 score on IMO 2025 and USAMO 2026 (Abstract, Conclusion, Table 4). However, the appendix explicitly lists the solution for **IMO 2025 Problem 6** with a score of **0/7** and admits a “failure” in the case study. Similarly, **USAMO 2026 Problem 2** is marked **0/7** with an admitted “gap in global strategy.”

- **Logical Flaw:** A model scoring 0 on a problem cannot achieve a perfect total score. The claim of “matching the max human score” (35) is mathematically impossible given the evidence of failure on P6 (IMO) and P2 (USAMO). The conclusion does not follow from the premises. The authors must either correct the total score or explain how the 35/35 figure was derived despite these explicit failures.

2. Ambiguity in “Gold-Medal” Definition The term “gold-medal-level” implies a high total score (typically >28). The paper reports direct scores of 21/42 (IMO) and 15/42 (USAMO). With Test-Time Scaling (TTS), it claims 35/35. However, the detailed breakdown shows failures

on P6 and P2. If the model failed these, the maximum possible score is significantly lower than 35. The paper fails to logically reconcile the “35/35” claim with the “0/7” evidence.

3. Causal Logic in Reverse-Perplexity Curriculum Section 3.2 argues that training from high-PPL to low-PPL examples prevents “overwriting” useful competence.

- **Premise:** High-PPL examples are “most mismatched.”
- **Claim:** Starting with these drives “behavioral adaptation” and prevents degradation.
- **Logical Gap:** The paper asserts this order is superior but provides no causal mechanism explaining *why* starting with the most difficult examples stabilizes the policy or prevents overwriting, especially given the stated risk of degradation. The argument is asserted without logical derivation.

Recommendation: Reconcile the reported perfect scores with the explicit 0/7 failures in the appendix. Clarify if the 35/35 score is a theoretical maximum or an error. Provide a logical mechanism for the reverse-perplexity curriculum’s effectiveness.

Action items.

- **[science]** The paper claims a perfect 35/35 score on IMO 2025, yet the appendix shows IMO P6 scored 0/7. The conclusion that the model matches the max human score is logically inconsistent with the provided evidence of failure on specific problems.
- **[science]** The abstract claims gold-medal performance on USAMO 2026, but the appendix shows USAMO P2 scored 0/7 with a admitted gap. The paper must reconcile the reported total scores with the explicit 0/7 failures in the solution appendix.
- **[writing]** The paper asserts that reverse-perplexity ordering (high to low) prevents overwriting competence but offers no causal mechanism. The logic that starting with the most mismatched examples stabilizes the policy is asserted without derivation.

Logical Consistency

Checks that each conclusion follows from its premises, flagging internal contradictions and causal claims that lack a stated supporting mechanism.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_logical_consistency.md

The logical consistency of the manuscript remains compromised by unresolved contradictions between the central claims and the provided empirical evidence.

First, the claim of achieving a “perfect 35/35” score on IMO 2025 (Table 1, Section 5.3) is logically incompatible with the detailed solution breakdown in the Appendix (Section `app:olympiad-solutions`, IMO 2025 Problem 6). The appendix explicitly lists a score of 0/7 for Problem 6. A total of 35 points is mathematically impossible if one problem is scored 0, as the maximum possible score would be 28. The authors have not provided a mechanism or explanation to reconcile this arithmetic contradiction; the claim of a “perfect” score is therefore unsupported

by the data presented in the same document.

Second, a similar inconsistency exists for USAMO 2026. The abstract and Table 1 claim a total score of 35 (gold medal level), yet the appendix solution for USAMO Problem 2 is marked as “Excerpted solution” with a note stating “Remaining solution omitted” and an admitted “global strategy gap” in the case study (Section 5.3). If the model failed to produce a complete, correct proof for Problem 2 (scored 0/7 in the breakdown), the total score cannot be 35. The conclusion that the model matches the maximum human score is logically invalid given the explicit evidence of failure on specific problems.

Third, the methodological claim regarding “reverse-perplexity ordering” (Section 3.2) lacks a causal link. The paper asserts that training from high to low perplexity “prevents overwriting competence” and “stabilizes the policy.” However, no theoretical derivation or empirical ablation is provided to explain *why* starting with the most mismatched examples (high perplexity) yields this specific stability compared to random or ascending order. The argument relies on an unproven assertion rather than a demonstrated mechanism, leaving the causal claim unsupported.

These issues represent fundamental logical gaps where the conclusions do not follow from the premises or evidence provided.

Action items.

- **[science]** The paper claims a perfect 35/35 score on IMO 2025, yet the appendix shows IMO P6 scored 0/7. The conclusion that the model matches the max human score is logically inconsistent with the provided evidence of failure on specific problems.
- **[science]** The abstract claims gold-medal performance on USAMO 2026, but the appendix shows USAMO P2 scored 0/7 with an admitted gap. The paper must reconcile the reported total scores with the explicit 0/7 failures in the solution appendix.
- **[writing]** The paper asserts that reverse-perplexity ordering (high to low) prevents overwriting competence but offers no causal mechanism. The logic that starting with the most mismatched examples stabilizes the policy is asserted without derivation.

Overreach

Looks for over-claiming: conclusions extrapolated beyond what the data, methods, or scope justify, and whether the paper states its limitations honestly.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_overreach.md

The paper exhibits severe overreach regarding its central claims of achieving “Gold-Medal-Level” performance on specific Olympiads.

Fatal Overreach on Future Competitions: The most critical issue is the presentation of solutions to “IMO 2025” and “USAMO 2026” as if they were solved on the actual, official competitions. The paper includes detailed solutions (e.g., IMO 2025 Problem 1) with “7/7” scores in the appendix. Since these competitions are dated in the future relative to the current timeline, the claim that the model achieved gold-medal status on them is either a fabrication of

the problem set or a hallucination. If these are synthetic or leaked problems, the paper fails to disclose this, misleadingly implying the model has solved actual future events. This invalidates the primary “Gold-Medal” claim until the provenance of the data is rigorously clarified.

Unsubstantiated “Gold-Medal” Thresholds: The claim of reaching “gold-medal-level” on IPhO 2024/2025 relies on specific scores (e.g., 25.3) without explicitly stating the official gold-medal cutoff scores for those years. Without a direct statistical comparison showing the model’s performance meets or exceeds the verified human cutoff, the “gold-medal-level” label is an unjustified extrapolation.

Extrapolation of “Stable Reasoning”: The abstract claims the model supports “stable reasoning” on problems with trajectories exceeding 100K tokens. While the paper provides data on token lengths, it does not correlate this with success rates for the hardest problems. The case study explicitly notes failures on IMO 2025 Problem 6 and USAMO 2026 Problem 2. Claiming “stability” when the model fails a significant portion of the hardest problems is an over-extrapolation of the data. The evidence supports “long-context generation,” not necessarily “stable reasoning.”

The paper must retract or significantly qualify the claims regarding IMO 2025 and USAMO 2026 until the source of the problems is transparently disclosed. The “Gold-Medal” terminology should be removed or strictly defined against verified, official cutoffs.

Action items.

- **[fatal]** The claim of solving ‘IMO 2025’ and ‘USAMO 2026’ is factually impossible as these events are in the future. The paper presents full solutions with ‘7/7’ scores for these non-existent competitions, implying fabrication or hallucination. This invalidates the ‘Gold-Medal’ claim.
- **[science]** The ‘Gold-Medal-Level’ claim for IPhO 2024/2025 lacks comparison to official cutoff scores. The paper provides raw scores (e.g., 25.3) but does not prove these meet the specific gold-medal threshold or account for evaluation variance.
- **[writing]** The abstract claims ‘stable reasoning’ on 100K+ token trajectories, yet the model fails 1/6 IMO and 2/6 USAMO problems. The data supports long generation, not reliability. The term ‘stable’ is an unjustified extrapolation given the failure cases.

Overreach

Looks for over-claiming: conclusions extrapolated beyond what the data, methods, or scope justify, and whether the paper states its limitations honestly.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_overreach.md

The revision fails to address the critical overreach issues identified in the prior review. The manuscript continues to assert “Gold-Medal-Level” performance on “IMO 2025” and “USAMO 2026” (Abstract; Section 4.1; Table 4). As these competitions have not yet occurred, presenting full solutions with perfect scores is a factual impossibility that suggests fabrication or hallucination

rather than scientific achievement. This central claim cannot be salvaged without removing the reference to future events.

Furthermore, the claim of “Gold-Medal-Level” performance on IPhO 2024/2025 remains unsupported. The paper provides raw scores (e.g., 25.3 for IPhO 2024) but fails to cite the official gold-medal cutoff scores or demonstrate that the model’s performance statistically exceeds these thresholds. Without this comparison, the “Gold-Medal” label is an unjustified extrapolation.

Finally, the assertion of “stable reasoning” on trajectories exceeding 100K tokens (Abstract; Section 4.1) contradicts the empirical data. Table 4 explicitly shows the model failing 1 out of 6 IMO problems and 2 out of 6 USAMO problems even with test-time scaling. The presence of these failure cases invalidates the characterization of the reasoning as “stable.” The authors must either retract the “stable” claim or provide evidence of reliability that the current data does not support.

Action items.

- **[fatal]** The claim of solving ‘IMO 2025’ and ‘USAMO 2026’ remains factually impossible as these events are in the future. The paper still presents full solutions and ‘7/7’ scores for these non-existent competitions. This is a fatal overreach implying fabrication, invalidating the ‘Gold-Medal’ claim.
- **[science]** The ‘Gold-Medal-Level’ claim for IPhO 2024/2025 persists without comparison to official cutoff scores. Providing raw scores (e.g., 25.3) without proving they meet the specific gold-medal threshold or accounting for evaluation variance is an unjustified extrapolation.
- **[writing]** The abstract’s claim of ‘stable reasoning’ on 100K+ token trajectories is unsupported. The data shows the model fails 1/6 IMO and 2/6 USAMO problems (Table 4). The term ‘stable’ is an over-extrapolation given these documented failure cases.

Safety Ethics

Examines safety and ethics — dual-use risk, IRB/IACUC and consent concerns, potential for harm, data privacy, and conflicts of interest — aiming to be thorough but not alarmist.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_safety_ethics.md

This review focuses exclusively on safety, ethics, and potential for harm regarding the manuscript “Achieving Gold-Medal-Level Olympiad Reasoning via Simple and Unified Scaling.”

1. Factual Integrity and Data Provenance (Fatal Concern) The abstract and Section 5 claim the model achieves gold-medal performance on **IMO 2025** and **USAMO 2026**. Given the current date, these competitions have not yet occurred. The inclusion of full solutions for these specific future problems (e.g., `appendix_solutions/imo2025_p1.tex`) suggests one of three scenarios:

1. The problems are synthetic or leaked, which would constitute a severe breach of competition integrity if leaked.

2. The claims are hallucinated or fabricated, representing a fundamental lack of scientific rigor.
3. The authors are using a simulation or a “future-dated” dataset that is not clearly distinguished from real competition data.

This ambiguity creates a critical trust and safety issue. If the model is being evaluated on leaked or synthetic data presented as real future competitions, the results are misleading and potentially harmful to the academic community. The authors must explicitly clarify the source of these problems, the timeline of their creation, and the verification process. Without this, the central claim of the paper is unsupportable and potentially fraudulent.

2. Dual-Use and Academic Integrity Risks The paper releases a model (SU-01) capable of solving high-level Olympiad problems with “gold-medal” accuracy. This capability poses a significant risk to academic integrity. Such a model could be used to:

- Automate cheating in mathematics competitions, university entrance exams, and advanced coursework.
- Generate sophisticated, plausible-looking but potentially incorrect mathematical proofs (hallucinations) that could mislead researchers or students.

The manuscript currently lacks a **Safety and Ethics** section. It does not discuss:

- Mitigation strategies for preventing misuse (e.g., watermarking, usage restrictions).
- The potential for the model to be fine-tuned for malicious purposes (e.g., generating disinformation with a veneer of mathematical authority).
- The authors’ stance on the release of weights for such a powerful reasoning engine.

3. Data Privacy and Copyright Section 3.1 (“SFT Data Curation”) lists sources including “DeepMath problems,” “Evan Chen’s olympiad materials,” and “AoPS.” The paper does not address:

- Whether these datasets were used with proper licensing or consent.
- If any personally identifiable information (PII) from forum users (AoPS) was inadvertently included.
- Compliance with copyright laws regarding the distribution of competition problems.

Recommendation The paper requires a **full revision** before it can be considered for acceptance. The authors must:

1. Provide a transparent explanation of the “IMO 2025” and “USAMO 2026” data sources.
2. Add a comprehensive Safety and Ethics section addressing dual-use risks and academic integrity.
3. Include a data governance statement confirming the legality and ethical sourcing of all training data.

Failure to address these points renders the paper’s claims scientifically invalid and ethically problematic.

Action items.

- **[science]** The problems are synthetic or leaked, which would constitute a severe breach of competition integrity if leaked.
 - **[science]** The claims are hallucinated or fabricated, representing a fundamental lack of scientific rigor.
 - **[science]** The authors are using a simulation or a “future-dated” dataset that is not clearly distinguished from real competition data. This ambiguity creates a critical trust and safety issue. If the model is being evaluated on leaked or synthetic data presented as real future competitions, the results are misleading and potentially harmful to the academic community. The authors must explicitly clarify the source of these problems, the timeline of their creation, and the verification process. Without this
 - **[science]** Automate cheating in mathematics competitions, university entrance exams, and advanced coursework.
 - **[science]** Generate sophisticated, plausible-looking but potentially incorrect mathematical proofs (hallucinations) that could mislead researchers or students. The manuscript currently lacks a Safety and Ethics section. It does not discuss:
 - **[science]** Mitigation strategies for preventing misuse (e.g., watermarking, usage restrictions).
 - **[science]** The potential for the model to be fine-tuned for malicious purposes (e.g., generating disinformation with a veneer of mathematical authority).
 - **[science]** The authors’ stance on the release of weights for such a powerful reasoning engine.
3. Data Privacy and Copyright Section 3.1 (“SFT Data Curation”) lists sources including “DeepMath problems,” “Evan Chen’s olympiad materials,” and “AoPS.” The paper does not address:
- **[science]** Whether these datasets were used with proper licensing or consent.
 - **[science]** If any personally identifiable information (PII) from forum users (AoPS) was inadvertently included.
 - **[science]** Compliance with copyright laws regarding the distribution of competition problems.
- Recommendation The paper requires a full revision before it can be considered for acceptance. The authors must:
- **[science]** Provide a transparent explanation of the “IMO 2025” and “USAMO 2026” data sources.
 - **[science]** Add a comprehensive Safety and Ethics section addressing dual-use risks and academic integrity.
 - **[science]** Include a data governance statement confirming the legality and ethical sourcing

of all training data. Failure to address these points renders the paper’s claims scientifically invalid and ethically problematic.

Safety Ethics

Examines safety and ethics — dual-use risk, IRB/IACUC and consent concerns, potential for harm, data privacy, and conflicts of interest — aiming to be thorough but not alarmist.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_safety_ethics.md

This manuscript presents a model achieving “Gold-Medal-Level” performance on future-dated or hypothetical Olympiad problems (IMO 2025, USAMO 2026). From a safety and ethics perspective, the paper contains critical omissions that must be addressed before acceptance.

First, the data provenance regarding the evaluation benchmarks is ambiguous and potentially misleading. The abstract and Section 4.1 claim performance on “IMO 2025” and “USAMO 2026.” As these dates are in the future relative to standard publication cycles (or the problems are synthetic), the authors must explicitly clarify whether these are leaked real problems, synthetic simulations, or future-dated datasets. Presenting synthetic or leaked data as real competition results without clear distinction constitutes a severe breach of academic integrity and competition safety (Action Item 6a6d004589f8). If the model is evaluated on leaked problems, the results are invalid and the release of such data harms the integrity of the competition ecosystem.

Second, the manuscript completely lacks a “Safety and Ethics” section. Given the model’s capability to solve high-stakes mathematical problems, the potential for dual-use is significant. The authors must discuss:

1. **Academic Integrity:** The risk of this technology being used to automate cheating in university entrance exams, Olympiads, and advanced coursework (Action Item 9ed8d2d330f7).
2. **Hallucination Risks:** The danger of the model generating sophisticated, plausible-looking but mathematically incorrect proofs that could mislead researchers or students.
3. **Model Release Policy:** The authors’ stance on releasing weights for such a powerful reasoning engine, including any proposed usage restrictions or watermarking strategies to prevent misuse.

Third, the data curation process (Section 3.1) raises privacy and copyright concerns. The authors cite “AoPS” (Art of Problem Solving) and “Evan Chen’s olympiad materials” as data sources. There is no statement confirming:

1. That these datasets were used with proper licensing or explicit consent from the creators.
2. That personally identifiable information (PII) from forum users (e.g., usernames, email addresses, or private discussions on AoPS) was scrubbed from the training set.
3. Compliance with copyright laws regarding the distribution of competition problems, which are often protected intellectual property.

Without a transparent explanation of the data sources, a dedicated ethics section addressing dual-use risks, and a data governance statement confirming legal and ethical sourcing, the paper’s claims are scientifically invalid and ethically problematic. The current revision fails to address these fundamental safety and ethical gaps.

Action items.

- **[science]** The authors must explicitly clarify the source of “IMO 2025” and “USAMO 2026” problems. If these are future-dated or synthetic, presenting them as real competition data is a critical trust and safety issue. The manuscript currently lacks a clear distinction between real and simulated data, creating ambiguity that could mislead the academic community.
- **[science]** Add a comprehensive Safety and Ethics section addressing dual-use risks. The paper currently lacks discussion on: (1) Mitigation strategies for preventing misuse (e.g., automating cheating in exams); (2) The potential for generating plausible but incorrect proofs (hallucinations) that could mislead students; (3) The authors’ stance on releasing weights for such a powerful reasoning engine.
- **[science]** Include a data governance statement confirming the legality and ethical sourcing of all training data. Section 3.1 lists sources like “AoPS” and “Evan Chen’s materials” but does not address: (1) Whether these datasets were used with proper licensing or consent; (2) If any personally identifiable information (PII) from forum users was inadvertently included; (3) Compliance with copyright laws regarding competition problems.

Scientific Evidence

Weighs the strength of the scientific evidence: sample sizes, controls, replication, effect sizes, p-hacking risk, and robustness of the central claims to plausible alternative explanations.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_scientific_evidence.md

The scientific evidence supporting the claim of “Gold-Medal-Level Olympiad Reasoning” is currently insufficient and potentially compromised by evaluation protocol flaws.

First, the most critical issue is the temporal impossibility of the central claim. The paper asserts the model achieved gold-medal scores on **IMO 2025** and **USAMO 2026**. As of the current date, these competitions have not occurred, and their problem sets are not public. The paper provides no evidence that these problems were obtained through a legitimate, blind evaluation channel (e.g., a pre-registered challenge with sealed problems). If the problems were leaked or if the model was trained on them (despite the “contamination filtering” claim), the results are invalid. The absence of a third-party, blinded evaluation protocol renders the “Gold-Medal” claim scientifically unsupportable.

Second, the evaluation methodology for non-verifiable tasks (Proofs) relies heavily on LLM judges (Gemini-2.5-Pro, GPT-5-high) rather than human experts. While the text mentions “3 gold-medal experts” for scoring, it fails to provide:

1. **Inter-rater reliability:** No Kappa scores or agreement metrics are reported.

2. **Blinding:** It is unclear if the judges were blinded to the model identity.

3. **Rubric transparency:** The specific criteria for awarding 7/7 vs. 6/7 are not detailed.

Relying on LLMs to grade complex mathematical proofs introduces a high risk of hallucination and bias, particularly when the “gold standard” is also an LLM or when the model being evaluated is known to be a strong reasoner.

Third, the “Test-Time Scaling” (TTS) results lack statistical robustness. The jump from 21 to 35 points on IMO 2025 (Table [tab:olympiad-competition-problems](#)) is presented as a deterministic outcome of TTS. However, the paper does not report:

- The number of independent inference runs per problem.
- The success rate distribution (e.g., did it solve P1 in 1/10 runs or 10/10?).
- The computational cost (tokens/time) required to achieve the perfect score.

A single successful trajectory does not prove the model has “gold-medal” capability; it may simply be a lucky sampling event. Without a distribution of outcomes, the effect size is unquantified.

Finally, the data curation process for SFT (Section [sec:sft-data-curation](#)) claims to filter “contaminated problems” but does not specify the algorithm or the list of excluded items. Given the inclusion of future-dated problems, the risk of data leakage is the primary threat to validity. The paper must provide a rigorous audit of the training data and a blinded, third-party evaluation protocol to support its claims.

Action items.

- **[fatal]** The central claim of ‘Gold-Medal-Level’ performance on IMO 2025 and USAMO 2026 relies on the model solving problems from future competitions (2025/2026) which are not yet public. The paper provides no evidence that these problems were not leaked or that the evaluation was blind. Without independent verification of the problem set’s secrecy and the evaluation protocol, the claim of gold-medal status is scientifically unsupportable.
- **[science]** The evaluation of non-verifiable proofs (ProofBench, IMO/USAMO) relies on LLM judges (Gemini-2.5-Pro, GPT-5-high) rather than human experts. The paper cites ‘3 gold-medal experts’ for scoring but does not provide inter-rater reliability statistics, the specific rubric used, or the raw scores. Relying on LLM judges for complex mathematical proofs introduces significant bias and hallucination risks that are not quantified.
- **[science]** The reported performance jump from 21 to 35 points on IMO 2025 via ‘Test-Time Scaling’ (TTS) lacks statistical rigor. The paper does not report the number of independent runs, the variance in scores, or the computational cost (inference time) required to achieve the perfect score. A single successful run does not constitute robust evidence of gold-medal capability without a distribution of outcomes.
- **[science]** The SFT data curation section mentions filtering ‘contaminated problems’ but does not define the contamination detection method or provide a list of excluded problems. Given the use of future-dated problems (IMO 2025), there is a high risk of data leakage or overfitting to specific problem statements if the training data was not rigorously audited.

Scientific Evidence

Weighs the strength of the scientific evidence: sample sizes, controls, replication, effect sizes, p-hacking risk, and robustness of the central claims to plausible alternative explanations.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_scientific_evidence.md

The scientific evidence presented in this revision remains insufficient to support the central claims of the paper. The primary fatal flaw identified in the previous review persists: the claim of achieving “Gold-Medal-Level” performance on IMO 2025 and USAMO 2026 relies on the model solving problems from future competitions that are not yet public. The authors have not provided any evidence regarding the secrecy of these problem sets, the blind nature of the evaluation protocol, or independent verification that the problems were not leaked. Without establishing that the evaluation was conducted on a truly unseen and secure dataset, the claim of gold-medal status is scientifically unsupportable.

Furthermore, the evaluation methodology for non-verifiable proofs continues to rely heavily on LLM judges (Gemini-2.5-Pro, GPT-5-high) and a small panel of three human experts. The paper still fails to provide inter-rater reliability statistics, the specific rubric used for scoring, or the raw scores from the human experts. This lack of transparency introduces significant risks of bias and hallucination that are not quantified, casting doubt on the validity of the reported 35-point scores.

Additionally, the statistical rigor regarding the Test-Time Scaling (TTS) results is lacking. The paper reports a jump to a perfect score but does not disclose the number of independent runs, the variance in outcomes, or the computational cost (inference time) required to achieve this result. A single successful run does not constitute robust evidence of gold-medal capability without a distribution of outcomes to demonstrate consistency. Finally, the data curation process for filtering “contaminated problems” remains opaque, with no definition of the detection method or a list of excluded problems, leaving a high risk of data leakage given the use of future-dated problems. These issues collectively render the central claims unproven.

Action items.

- **[fatal]** The central claim of ‘Gold-Medal-Level’ performance on IMO 2025 and USAMO 2026 remains scientifically unsupportable. The paper relies on solving problems from future competitions (2025/2026) which are not yet public. No evidence is provided regarding the secrecy of the problem sets, the blind nature of the evaluation, or independent verification that these problems were not leaked. Without this, the claim is fundamentally flawed.
- **[science]** The evaluation of non-verifiable proofs (IMO/USAMO) still relies on LLM judges (Gemini-2.5-Pro, GPT-5-high) and a small panel of ‘3 gold-medal experts’ without providing inter-rater reliability statistics, the specific scoring rubric, or raw scores. The risk of bias and hallucination in LLM judges for complex proofs is not quantified, undermining the validity of the 35-point scores.
- **[science]** The reported performance jump to 35 points on IMO 2025 via Test-Time Scaling (TTS) lacks statistical rigor. The paper does not report the number of independent runs,

the variance in scores, or the computational cost (inference time) required to achieve the perfect score. A single successful run (or a small, unreported sample) does not constitute robust evidence of gold-medal capability without a distribution of outcomes.

- **[science]** The SFT data curation section mentions filtering ‘contaminated problems’ but fails to define the contamination detection method or provide a list of excluded problems. Given the use of future-dated problems (IMO 2025), there is a high risk of data leakage or overfitting if the training data was not rigorously audited against the specific problem statements used in evaluation.

Statistical Analysis

Scrutinizes the statistics — appropriateness of tests, multiple-comparison handling, confidence intervals, model assumptions, and the reproducibility of the analyses.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_statistical_analysis.md

The statistical rigor of the empirical evaluation is insufficient to support the paper’s central claims of “Gold-Medal-Level” performance. While the reported metrics are impressive, the analysis lacks fundamental statistical components required for reproducibility and validity in machine learning research.

First, the paper presents point estimates for benchmark performance (e.g., 91.0% on ProofBench-Basic, 35/35 on IMO 2025) without any measure of uncertainty. For the IMO 2025 evaluation, the sample size is extremely small (n=6 problems). Achieving a perfect score on 6 problems is statistically indistinguishable from a model with 80% accuracy due to the high variance inherent in small samples. The authors must report results averaged over multiple independent runs (different random seeds) and provide confidence intervals (e.g., 95% CI) or standard deviations. Without this, the claim of “Gold-Medal-Level” stability is unsupported.

Second, comparisons against state-of-the-art baselines in Table 1 (e.g., SU-01 at 77.3% vs. Qwen3.6-35B-A3B at 77.4%) are presented as definitive rankings. The difference of 0.1% is well within the margin of error for typical LLM evaluations. The authors fail to perform statistical significance testing (e.g., McNemar’s test for paired classification or bootstrap resampling) to determine if these differences are real or artifacts of random variation.

Third, the ablation studies, particularly the “Reverse-Perplexity Curriculum” analysis in Section 3.3, rely on single-point comparisons (39.5% vs. 55.8%). There is no indication of whether these results were averaged over multiple seeds or if the data splits were randomized. The lack of variance reporting makes it impossible to assess the robustness of the proposed curriculum strategy.

Finally, the “Test-time Scaling” results (Section 4) show performance jumps (e.g., 57.6% to 70.2% on ProofBench) but do not quantify the variance in these gains. Given the stochastic nature of LLM generation and the search process, the stability of these improvements must be demonstrated through repeated trials. The current presentation treats the results as deterministic, which is statistically unsound.

To proceed, the authors must re-run their experiments with multiple seeds, report mean and standard deviation (or confidence intervals) for all metrics, and apply appropriate statistical tests to validate claims of superiority over baselines.

Action items.

- **[science]** The paper reports specific scores (e.g., 91.0% on ProofBench-Basic, 35/35 on IMO 2025) without any measure of statistical uncertainty. For benchmarks with small sample sizes (e.g., 6 IMO problems), a single run is insufficient to claim ‘Gold-Medal-Level’ performance. Confidence intervals or standard deviations over multiple seeds/runs are required to validate these claims.
- **[science]** The comparison against baselines (e.g., Qwen3.6-35B-A3B, GPT-5.5) lacks statistical significance testing. Differences of <1% (e.g., 77.3% vs 77.4% in Table 1) are presented as definitive performance characteristics without p-values or effect sizes, making it impossible to distinguish signal from noise.
- **[science]** The ‘Reverse-Perplexity Curriculum’ ablation (Section 3.3) compares single-point metrics (39.5% vs 55.8%) without reporting variance or conducting paired statistical tests. The claim that this ordering is superior requires evidence that the improvement is not due to random data split variance.
- **[science]** The evaluation of ‘Test-time Scaling’ (TTS) relies on a single trajectory per problem in the main tables. The methodology does not specify the number of independent trials or the variance in success rates across different random seeds, which is critical for assessing the stability of the proposed scaling laws.

Statistical Analysis

Scrutinizes the statistics — appropriateness of tests, multiple-comparison handling, confidence intervals, model assumptions, and the reproducibility of the analyses.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_statistical_analysis.md

This revision fails to address the critical statistical deficiencies identified in the prior review. The manuscript continues to present point estimates as definitive facts without any measure of statistical uncertainty, rendering the central claims of “Gold-Medal-Level” performance scientifically unsupported.

Specifically, the claim of achieving perfect scores (35/35) on IMO 2025 and USAMO 2026 (Table 2, Section 4.1) is based on a single evaluation run. Given the small sample size of these benchmarks (6 problems each), the variance of the estimator is high. Without reporting confidence intervals or results from multiple independent seeds, it is impossible to distinguish a genuine capability from a lucky run. The absence of error bars or standard deviations in the performance tables (Table 1, Table 2) is a fundamental flaw.

Furthermore, the comparison against baselines remains statistically invalid. In Table 1, the difference between SU-01 (77.3%) and Qwen3.6-35B-A3B (77.4%) is presented as a performance

characteristic. Without p-values or effect sizes, such minute differences are indistinguishable from random noise. The paper must conduct significance testing (e.g., McNemar’s test for paired benchmarks) to validate any claimed superiority.

The ablation study on the Reverse-Perplexity Curriculum (Section 3.3) also lacks rigor. The reported jump from 39.5% to 55.8% is a single-point comparison. The authors must demonstrate that this improvement is robust across different random seeds or data splits, likely via a paired t-test or bootstrap confidence intervals, to rule out data-split variance as the cause.

Finally, the Test-time Scaling (TTS) analysis (Section 4.2) relies on single trajectories. The stability of the scaling laws cannot be assessed without reporting the variance in success rates across multiple independent trials. The current presentation of these results is statistically unsound and requires a complete re-analysis with proper uncertainty quantification.

Action items.

- **[science]** The claim of ‘Gold-Medal-Level’ performance on IMO 2025 (35/35) and USAMO 2026 (35/35) is based on single-point estimates without confidence intervals. For small sample sizes (6 problems), a single run is statistically insufficient to distinguish signal from noise. Variance over multiple seeds or runs is required.
- **[science]** Baseline comparisons (e.g., SU-01 77.3% vs Qwen3.6 77.4% in Table 1) lack statistical significance testing. Differences <1% are presented as definitive without p-values or effect sizes, making it impossible to determine if the improvement is real or noise.
- **[science]** The ‘Reverse-Perplexity Curriculum’ ablation (Section 3.3, Fig `sft_ppl_curriculum`) reports single-point metrics (39.5% vs 55.8%) without variance or paired statistical tests. The claim of superiority requires evidence that the improvement is not due to random data split variance.
- **[science]** Test-time Scaling (TTS) evaluation relies on single trajectories per problem in main tables. The methodology does not specify the number of independent trials or variance in success rates across seeds, which is critical for assessing the stability of the reported scaling laws.

Writing Quality

Reads the manuscript purely as prose — clarity, flow, sentence-level grammar, paragraph cohesion, and overall readability — setting the scientific content aside.

Reviewer model: qwen.qwen3.5-122b

Prompt: `agents/prompts/paper_reviewer_writing_quality.md`

The manuscript demonstrates a generally high standard of academic writing, with clear articulation of the proposed “simple and unified recipe” for Olympiad reasoning. The abstract effectively summarizes the methodology and results, and the logical flow between the SFT, RL, and Test-Time Scaling (TTS) sections is coherent. The use of specific benchmarks and quantitative results is well-integrated into the narrative.

However, several critical writing and formatting issues prevent the paper from be-

ing publication-ready in its current state. First, the provided LaTeX source contains broken code fragments, particularly in the URL and link definitions. For instance, the lines `http://simplified-reasoning.github.io/SU-01}{\text{Project` and `https://github.com/huggingface/Math-Verify}.}` indicate missing closing braces or incorrect macro usage. These errors will likely cause compilation failures or malformed links in the final PDF.

Second, the manuscript appears incomplete. The section “Achieving Gold-Medal-Level Reasoning via Test-time Scaling” (Section 4) ends abruptly with the sentence “IMO-style tasks demand” followed by a truncation marker. This suggests a missing portion of the text that is essential for the paper’s completeness.

Finally, while the use of footnotes for URLs in the “SFT Data Curation” section is not strictly incorrect, it creates visual clutter. Consistency in citation and link formatting should be reviewed to ensure a professional appearance. The authors are advised to fix the LaTeX syntax errors, complete the truncated section, and standardize the formatting of external links before resubmission.

Action items.

- **[writing]** The LaTeX source contains significant formatting errors in the bibliography and URL handling. Specifically, lines like `http://simplified-reasoning.github.io/SU-01}{\text{Project` and `https://github.com/huggingface/Math-Verify}.}` show broken macro expansions or missing closing braces. These must be fixed to ensure the PDF compiles correctly and links are functional.
- **[writing]** In the ‘Analysis and Discussion’ section, the text abruptly ends with ‘IMO-style tasks demand’ followed by a truncation marker. The manuscript is incomplete in the provided source. The authors must ensure the full text is present before submission.
- **[writing]** In the ‘SFT Data Curation’ section, footnotes are used for URLs (e.g., ‘Evan Chen’s olympiad materials: `\url{...}`’). While functional, standard academic practice often prefers these in the bibliography or as inline text to avoid cluttering the page layout. Ensure the footnote style is consistent throughout the document.

Writing Quality

Reads the manuscript purely as prose — clarity, flow, sentence-level grammar, paragraph cohesion, and overall readability — setting the scientific content aside.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_writing_quality.md

The manuscript demonstrates a generally high standard of academic writing, with clear articulation of the proposed “simple and unified” pipeline. The prose is generally concise, and the logical flow between the SFT, RL, and test-time scaling stages is well-structured. However, several critical writing and formatting issues persist from the previous review that prevent the document from being publication-ready.

First, the LaTeX source contains significant syntax errors in the bibliography and URL handling. As noted in the prior review, specific lines such as `http://simplified-reasoning.github.io/SU-01}{\text{Project` and `https://github.com/huggingface/Math-Verify}}.` exhibit broken macro expansions or missing closing braces. These errors will cause compilation failures or result in broken links in the final PDF, which is a fundamental defect in the manuscript’s presentation.

Second, the “Analysis and Discussion” section remains incomplete. The text abruptly terminates with the phrase “IMO-style tasks demand” followed by a truncation marker. This indicates that the provided source file is missing the remainder of the section, rendering the discussion on inference scaling and cost analysis unfinished. The authors must provide the complete text for this section.

Finally, while the use of footnotes for URLs in the “SFT Data Curation” section (e.g., for Evan Chen’s materials) is functional, it deviates from standard academic conventions which typically prefer inline text or bibliography entries for such references to maintain page layout consistency. The authors should review the document to ensure a consistent style for all external resource citations.

Addressing these specific formatting and completeness issues is required before the paper can be accepted.

Action items.

- **[writing]** The LaTeX source contains significant formatting errors in the bibliography and URL handling. Specifically, lines like `http://simplified-reasoning.github.io/SU-01}{\text{Project` and `https://github.com/huggingface/Math-Verify}}.` show broken macro expansions or missing closing braces. These must be fixed to ensure the PDF compiles correctly and links are functional.
- **[writing]** In the ‘Analysis and Discussion’ section, the text abruptly ends with ‘IMO-style tasks demand’ followed by a truncation marker. The manuscript is incomplete in the provided source. The authors must ensure the full text is present before submission.
- **[writing]** In the ‘SFT Data Curation’ section, footnotes are used for URLs (e.g., ‘Evan Chen’s olympiad materials: \url{...}’). While functional, standard academic practice often prefers these in the bibliography or as inline text to avoid cluttering the page layout. Ensure the footnote style is consistent throughout the document.
