

llmXive Automated Review of Where Do Deep-Research Agents Go Wrong? Span-Level Error Localization in Agent Trajectories

llmXive automated review panel

Please read first — this review is fully automated and not checked by any human. It is written by free, open-weight LLM agents that read the paper once, so errors, misreadings, and inaccuracies are likely. Nothing here has been verified by a person. Treat every point below as a fast, fallible first-pass signal — not an authoritative assessment.

How this review was produced

This Reviewed Preprint was read by a panel of specialist llmXive LLM reviewers. Each reviewer is deliberately confined to a *single narrow lens* — writing, logic, statistics, and so on — and does not comment outside it, so that distinct concerns are surfaced independently rather than blurred into one overall score. The panel runs *once* over the paper. Every reviewer's exact instructions are public in the [llmXive agent-prompt library](#); each section below also links the specific prompt it used.

This report is advisory, automated feedback for the authors. llmXive does not modify the paper, and nothing is accepted or rejected on its basis — every point below is a suggestion the authors are free to weigh. Each reviewer's section also names the underlying model that produced it.

This paper's panel (9 lenses): Claim Accuracy, Figure Critic, Jargon Police, Logical Consistency, Overreach, Safety Ethics, Scientific Evidence, Statistical Analysis, and Writing Quality. Each lens is described in its own section below, alongside the model and the exact prompt it used.

Claim Accuracy

Verifies factual claims against their citations — whether each cited source actually supports the claim attributed to it, and whether any claim is stated more strongly than its evidence permits.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_claim_accuracy.md

The paper makes several strong quantitative claims regarding the performance of the proposed \textsc{DRIFT} framework. While the overall narrative is supported by the provided tables, there are specific instances where the text overstates the evidence or conflates different metrics.

The most significant issue is in the Abstract, where the authors state that \textsc{DRIFT} improves “first-error accuracy by up to 30 percentage points.” A review of Table 1 (tab/main_exp.tex) reveals that the maximum absolute improvement in First-Error Accuracy (FEA) is 18.50 percentage points (DeepSeek-V3.2 on the Easy split). The figure of ~30 percentage points corresponds to the F1 score improvements (e.g., +31.92 for DeepSeek-V3.2), not the FEA. This conflation of metrics in the abstract is misleading and must be corrected to accurately reflect the data.

Additionally, the description of the dataset construction in Section 3 (sections/traj_collection.tex) contains a minor ambiguity. The text mentions collecting from three benchmarks and then states, “we downsample it to 200 tasks, resulting in 465 tasks.” It is unclear if “it” refers to the BrowseComp subset specifically or the aggregate, and the breakdown of the 465 tasks across the three sources is not explicitly detailed in the text, though the final number is clear. Clarifying the contribution of each benchmark to the final 465-task corpus would strengthen the reproducibility of the data collection claim.

Finally, the paper relies on citations for model versions like “GPT-5.4” and “DeepSeek-V3.2” with 2025/2026 dates. While the bibliography provides these entries, the accuracy of these specific version numbers and their availability at the time of the study should be cross-referenced with the cited system cards to ensure no hallucination of model capabilities or versions has occurred in the experimental setup description.

Action items.

- [writing] Abstract claims ‘first-error accuracy by up to 30 percentage points’ but Table 1 shows max FEA gain is 18.50. The 30 figure matches F1 gains, not FEA. Correct this metric conflation.
- [writing] Section 3 states ‘downsample it to 200 tasks, resulting in 465 tasks’ without clarifying the breakdown of the 465 total across the three cited benchmarks (GAIA, XBench, BrowseComp).
- [writing] Section 4 cites ‘GPT-5.4’ and ‘DeepSeek-V3.2’ with 2025/2026 dates. Verify these specific version numbers and dates against the cited system cards to ensure they are not hypothetical.

Figure Critic

Inspects each figure directly — the rendered image alongside its caption — for clarity, axis labels and units, color choices, legibility at print scale, and whether the figure earns its place. This lens runs on a vision-capable model.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_figure_critic.md

Figure 1

Figure 1 is a clear and well-labeled screenshot of the annotation interface described in the caption. All key components—ordered semantic spans, LLM-assisted candidate errors, editable rationales, and final expert decisions—are visible and legible, effectively supporting the paper’s description of the data curation process.

Figure 2

The figure presents clear statistics on error burdens, but the bottom-left chart mislabels its x-axis with outcome categories (‘Failed’/‘Successful’) instead of the error-span categories defined in its title and legend. Additionally, the bottom-right chart uses ambiguous model family labels that lack specific definition.

Figure 3

The figure effectively visualizes stage-normalized error rates, but contains specific data plotting errors where the ‘Retrieve’ bar is missing despite a label, and the ‘Extract’ span count label contradicts its plotted position.

Figure 4

The figure presents effort metrics but suffers from a critical labeling mismatch where the x-axis omits two of the five frameworks defined in the legend. Additionally, the caption’s description of how colors and hatching map to data categories contradicts the specific assignments shown in the legend.

Figure 5

The figure is visually clear but scientifically incomplete as the ‘Claude-Sonnet-4.6’ series listed in the legend is not plotted. Additionally, the caption fails to define the specific modules corresponding to the x-axis labels.

Figure 6

The figure effectively visualizes the relative performance of DRIFT against baselines across error types, but it fails to provide a radial scale, rendering the absolute recall percentages unreadable. Additionally, the abbreviated axis labels lack definitions, hindering precise interpretation of the error categories.

Figure 7

The figure presents a sorted bar chart of F1 scores but fails to label the x-axis, making it impossible to identify the specific benchmarks or models associated with each bar. Additionally, the legend conflates method categories with specific model icons, creating ambiguity about what each bar represents.

Figure 8

The figure presents performance metrics for three models but fails to visualize the specific analyses promised in the caption (span complexity, token cost). Additionally, the y-axis lacks unit labels and the stacked bar components are undefined.

Figure 9

The figure presents a radar chart comparing model performance across error types, but it lacks a quantitative scale on the axes and the legend is insufficient to distinguish between the multiple model lines plotted, hindering precise interpretation of the recall improvements.

Figure 10

Figure 10 is a clear and well-structured schematic that effectively visualizes the DRIFT workflow described in the caption. The three main modules (Claim Keeper, Support Seeker, Dependency Tracer) are distinct, and the flow of data and logic is easy to follow with appropriate icons and labels.

Figure 11

Figure 11 is a clear and well-structured pipeline diagram that effectively visualizes the data curation process described in the caption. All stages, inputs, and outputs are legible, and the flow from trajectory collection to the final TELBench dataset is logical and easy to follow.

Figure 12

(no summary returned)
Action items.

- [science] Figure 2 (bottom-left): The x-axis labels ‘Failed’ and ‘Successful’ contradict the chart’s title ‘Error vs. Non-Error Span Composition’ and the legend (‘Error span’/‘Non-error span’). The bars should be labeled by the presence of error spans (e.g., ‘Has Error Span’ vs ‘No Error Span’) to match the data being visualized, rather than the final trajectory outcome used in the top-left chart.
- [science] Figure 2 (bottom-right): The x-axis labels ‘GPT’, ‘Claude’, and ‘Gemini’ are ambiguous. The caption mentions comparing ‘model families’, but these labels could refer to specific models or families without a clear definition in the figure or caption, making it difficult to interpret the ‘Error-Span Density’ comparison accurately.
- [science] Figure 3: The ‘Retrieve’ stage has a labeled error rate of 2.9% but no visible bar, making the data point illegible and the chart inconsistent.
- [science] Figure 3: The ‘Extract’ stage shows a line data label of 3,146 spans, but the corresponding gray circle is plotted near the x-axis (approx. 1k), contradicting the label and the trend.
- [science] Figure 4: The legend defines five frameworks (GPT, Claude, Gemini, MiroFlow, OAgent), but the x-axis labels only list three (GPT, Claude, Gemini). The bars for MiroFlow and OAgent are present in the plot but lack corresponding x-axis labels, making it impossible to identify which model family they belong to.
- [science] Figure 4: The caption states ‘Colors denote model families, while hatching distinguishes frameworks,’ but the legend maps colors to specific model names (GPT, Claude, Gemini) and hatching to specific framework names (MiroFlow, OAgent). This contradicts the caption’s claim that colors represent broad families and hatching represents frameworks, creating confusion about whether the bars represent models or frameworks.
- [science] Figure 5: The legend lists ‘Claude-Sonnet-4.6’ (triangle marker), but the plot lines for this model are missing from all three subplots (Precision, Recall, F1), making the ablation incomplete.
- [writing] Figure 5: The caption ‘Ablation of Modules’ is vague; it does not define what the x-axis categories (‘Bare’, ‘-A’, ‘-A-B’, ‘DRIFT’) represent in terms of specific module additions.
- [science] Figure 6: The radar chart lacks a radial axis scale (e.g., 0%, 25%, 50%, 75%, 100%). Without numerical tick marks or a legend indicating the scale, it is impossible to determine the absolute recall values or the magnitude of improvement claimed in the caption.
- [writing] Figure 6: The axis labels are abbreviated (e.g., ‘Source verif.’, ‘Constraint semantics’, ‘Entity disamb.’) without defining the full error type names in the caption or figure text, making it difficult to map the data to specific error categories.
- [science] Figure 7: The legend defines ‘Bare’, ‘Codex’, ‘Claude Code’, and ‘DRIFT’ as

methods, but the bars are colored by these methods while containing icons for specific models (e.g., GPT-5.4, DeepSeek-V3.2). This conflates the method (framework) with the model, making it impossible to distinguish if a bar represents a specific model's performance or an aggregate of the method.

- [science] Figure 7: The x-axis lacks labels. While the bars are sorted by value, there is no indication of which benchmark, model, or configuration each bar represents, rendering the specific data points uninterpretable.
- [writing] Figure 7: The legend is split into two disconnected blocks (top row for methods, second row for models) without a clear visual grouping or hierarchy, which is confusing given the bars combine both method colors and model icons.
- [science] Figure 8: The caption claims to examine 'robustness across model scale and span complexity' and 'token cost,' but the figure only displays 'Macro F1' and 'FEA' scores for three specific model variants (Qwen3-235B, 32B, 8B) across 'Easy' and 'Hard' splits. There is no data shown regarding span complexity, token cost, or a broader scale analysis beyond these three points.
- [writing] Figure 8: The y-axis lacks a unit label (e.g., '%'), and the legend does not specify what the stacked bar segments represent (e.g., confidence intervals, component contributions, or error types).
- [science] Figure 9: The radar chart displays 12 error types, but the legend only defines 6 model configurations (DeepSeek Bare, Claude Bare, Qwen Bare, Gemini Bare, GPT Bare, Claude - PRIFT). It is unclear which line corresponds to which model for the non-baseline models, or if the colors map consistently across the 12 types without explicit labeling on the lines.
- [writing] Figure 9: The axis labels (e.g., 'Source misuse', 'Constraint semantics') are abbreviated and lack units or scale markers (e.g., 0%, 25%, 50%, 75%, 100%), making it impossible to quantify the 'recall' values mentioned in the caption.
- [science] Figure 12 (e): The scatter plot's x-axis ('Traj Error Rate') and y-axis ('Frequency in Error Trials') are not clearly labeled with units or definitions, making it difficult to interpret the relationship between the two metrics.
- [writing] Figure 12 (d): The word cloud contains extremely small, illegible text (e.g., 'subtask', 'confirmed', 'year') that cannot be read even at full resolution, reducing its utility as a visual summary.
- [science] Figure 12 (g): The x-axis labels ('1' through '10') lack context — it is unclear whether these represent time steps, span indices, or another ordinal metric, and no axis title clarifies this.

Jargon Police

Flags needless jargon: terms with plainer equivalents, acronyms not defined at first use, and passages that needlessly exclude non-specialist readers.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_jargon_police.md

The manuscript relies heavily on specialized terminology from the agent research and NLP communities, which creates a barrier for non-specialist readers. The term “semantic spans” is central to the paper’s contribution but is never explicitly defined in plain language; it is used as a given concept in the Abstract and Introduction. Similarly, “trajectory” is used repeatedly to describe the agent’s process, but a more accessible term like “step-by-step process” or “sequence of actions” would improve readability.

The metric “first-error accuracy” (FEA) is introduced without definition, leaving readers to guess its specific meaning. The framework name “DRIFT” is described as “claim-centric,” but this descriptor is not explained. The term “backbone models” is used for the underlying LLMs, which is jargon specific to model architecture discussions. “Verified-1K” is used as a proper noun for a dataset subset without a descriptive explanation.

Additionally, “agentic” is used as an adjective (e.g., “agentic auditing”), which is a non-standard neologism that should be replaced with “agent-based.” “Backtraces” is a programming/debugging term that could be simplified to “traces back” or “follows the chain of.” The term “hard constraints” is used without clarifying what distinguishes them from other types of constraints in this context. Finally, “span-level” is used frequently; while “segment-level” or “step-level” might be more intuitive for a general audience, the current usage assumes familiarity with NLP annotation terminology. These terms should be defined or replaced to ensure the paper is accessible to a broader scientific audience.

Action items.

- [writing] Define ‘semantic spans’ at first use in the Abstract and Introduction. The term is used as a core unit of analysis but lacks a plain-English definition for non-specialists.
- [writing] Replace ‘backbone models’ with ‘base models’ or ‘underlying LLMs’ in the Abstract and Introduction. ‘Backbone’ is jargon that may confuse readers outside the specific architecture sub-field.
- [writing] Define ‘first-error accuracy’ (FEA) upon its first mention in the Abstract or Introduction. Currently, it appears as a metric without explanation of what it measures.
- [writing] Replace ‘trajectory’ with ‘sequence of actions’ or ‘step-by-step process’ in the Abstract. While common in agent literature, ‘trajectory’ is a specific technical term that excludes general readers.
- [writing] Define ‘claim-centric’ in the Abstract. The phrase describes the framework’s approach but is not immediately clear to a general audience.
- [writing] Replace ‘span-level’ with ‘segment-level’ or ‘step-level’ in the Abstract and

Introduction. ‘Span’ is a technical term from NLP/linguistics that may be opaque to broader audiences.

- [writing] Define ‘Verified-1K’ in the Abstract. The name implies a specific dataset subset but lacks a descriptive explanation of what it contains.
- [writing] Replace ‘backtraces’ with ‘traces back’ or ‘follows the chain of’ in the Introduction. ‘Backtrace’ is a debugging/programming term that may be jargon-heavy.
- [writing] Define ‘hard constraints’ in the Introduction. The term is used without context for what constitutes a ‘hard’ vs. ‘soft’ constraint in this specific task.
- [writing] Replace ‘agentic’ with ‘agent-based’ or ‘autonomous agent’ in the Introduction. ‘Agentic’ is a neologism that is not standard English and may confuse readers.

Logical Consistency

Checks that each conclusion follows from its premises, flagging internal contradictions and causal claims that lack a stated supporting mechanism.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_logical_consistency.md

The paper presents a logically sound argument for shifting deep-research agent evaluation from final outcomes to span-level process errors. The causal chain from “unsupported intermediate commitments” to “final failure” is well-supported by the case studies and the DRIFT methodology.

However, three logical inconsistencies regarding dataset scope and result generalization require clarification:

1. **Dataset Composition vs. Evaluation Scope:** Section 3.1 states the 2,790-trajectory corpus was generated using exactly three backbone models (GPT-5, Gemini-2.5-Pro, Claude-Sonnet-4.5). However, Section 4.1 evaluates TELBench using five model families, including Qwen and DeepSeek. The text does not logically explain how these additional models fit into the benchmark: were new trajectories generated for them (contradicting the fixed 2,790 count), or are they being evaluated on trajectories they did not generate? This ambiguity undermines the definition of TELBench as a static benchmark derived from a specific corpus.
2. **Annotation Workflow Ambiguity:** The description of the human annotation pipeline in Section 3.1 is internally inconsistent regarding personnel. It mentions “two expert annotators” validating LLM candidates, then later states “seven expert annotators each spent over 300 hours.” It is unclear if the “two” are a subset of the “seven” or if the “seven” includes those who performed the initial LLM-assisted review. This lack of clarity obscures the logical flow of the quality assurance process.
3. **Over-generalization of Baseline Results:** In Section 4.2, the authors claim that generic

frameworks like Codex “can even degrade performance.” While Table 1 shows degradation for DeepSeek, it shows a marginal F1 improvement for GPT-5.4 (34.48 vs 33.93). The conclusion that these frameworks degrade performance is not universally supported by the presented data and should be qualified to reflect model-specific variability.

Addressing these points will strengthen the logical consistency of the experimental setup and the validity of the conclusions drawn.

Action items.

- [science] Clarify if Qwen/DeepSeek trajectories are part of the 2,790 corpus or new runs. Section 3.1 claims 3 models were used for collection, but Section 4.1 evaluates 5 models. The logical link between the fixed benchmark and the expanded evaluation set is missing.
- [writing] Define the roles of the ‘two’ vs ‘seven’ expert annotators in Section 3.1. The text mentions two experts validating LLM candidates and seven experts total spending 300 hours each. The workflow distribution is ambiguous.
- [writing] Qualify the claim that baselines ‘degrade performance’ in Section 4.2. Table 1 shows Codex improves GPT-5.4 slightly, contradicting the blanket statement. Specify that degradation is model-dependent.

Overreach

Looks for over-claiming: conclusions extrapolated beyond what the data, methods, or scope justify, and whether the paper states its limitations honestly.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_overreach.md

The paper makes a compelling case for span-level error localization, but several claims in the abstract and introduction slightly overreach the specific empirical evidence provided, particularly regarding the magnitude of improvement on the most difficult cases and the generalizability of the findings.

First, the abstract highlights an improvement of “up to 30 percentage points” in span-level error localization. While Table 1 (Main Results) does show a 31.92 point F1 gain for DeepSeek-V3.2 on the *Easy* split, the gain on the *Hard* split is significantly lower (22.26 points for DeepSeek, and even lower for others). More critically, the paper’s central diagnostic question is “Where do agents go wrong?” which implies identifying the *first* error. The “First-error accuracy” (FEA) metric tells a different story: for DeepSeek on the *Hard* split, the FEA gain is only 5.75 percentage points (from 1.75 to 7.50). By leading with the aggregate F1 gain, the abstract risks overstating the framework’s ability to solve the core temporal localization problem, especially in the challenging scenarios the paper aims to address. The claim should be nuanced to reflect that while aggregate detection improves significantly, pinpointing the *initial* failure remains a substantial challenge with more modest gains.

Second, the introduction and conclusion generalize the findings to “deep-research agents” broadly. The dataset is constructed from three specific benchmarks (GAIA, X Bench, BrowseComp) and two frameworks (MiroFlow, OAgent). While these are representative, the specific failure modes identified (e.g., “unsupported commitments,” “candidate scope errors”) and the efficacy of the DRIFT framework are empirically grounded in this specific subset of tasks. The claim that “errors often emerge when weakly supported claims are repeatedly reused” is well-supported by the case studies, but presenting it as a universal law for all deep-research agents without qualifying the scope of the benchmarks used is a slight overreach. The conclusion should explicitly acknowledge that these insights are derived from the specific corpus of GAIA, X Bench, and BrowseComp tasks, and that other deep-research domains (e.g., code-heavy or purely mathematical reasoning) might exhibit different error propagation dynamics.

Finally, the claim that “scaling alone is insufficient” (Section 4.2) is supported by the Qwen scale analysis, but the data shows that for some models (like GPT-5.4), the Bare baseline actually performs quite well on the Easy split, and the gap between models is not always monotonic. The statement is a strong takeaway, but the evidence suggests that the *structure* of the audit (DRIFT) is more important than scale, rather than scale being entirely “insufficient.” A more precise phrasing would be that “architectural structure in auditing is more critical than backbone scale for reliable trajectory diagnosis,” which better captures the nuance that larger models still benefit from the proposed structure.

Action items.

- [writing] The abstract claims DRIFT improves localization by ‘up to 30 percentage points.’ While true for the Easy split (31.92), the Hard split gain is lower (22.26). Clarify that the 30pp gain applies specifically to the Easy split to avoid over-emphasizing performance on difficult cases.
- [writing] The abstract highlights a 30pp F1 gain but downplays the modest First-Error Accuracy (FEA) gains on the Hard split (e.g., only 5.75pp for DeepSeek). Since the paper’s core question is ‘Where do agents go wrong?’, the abstract over-represents success by focusing on aggregate F1 rather than the harder temporal localization metric.
- [writing] The introduction generalizes findings to ‘deep-research agents’ broadly, but the data is limited to three benchmarks (GAIA, X Bench, BrowseComp) and two frameworks. Temper the claim to acknowledge the specific scope of the corpus to avoid over-generalizing failure modes to all agent types.

Safety Ethics

Examines safety and ethics — dual-use risk, IRB/IACUC and consent concerns, potential for harm, data privacy, and conflicts of interest — aiming to be thorough but not alarmist.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_safety_ethics.md

The paper addresses a critical safety and reliability issue: the inability of current evaluation metrics to detect *how* deep-research agents fail, specifically focusing on “harmful error spans” that propagate through a trajectory. The proposed TELBench and DRIFT framework are well-aligned with safety goals, as they aim to improve the interpretability and auditability of agent decision-making processes.

However, there are specific ethical and procedural gaps in the data collection and annotation description that require clarification before the work can be fully accepted from a safety/ethics perspective:

1. **Annotator Bias and Conflict of Interest:** In the Appendix (Section “Annotation Guidelines and Annotator Information”), the authors state that the seven expert annotators were “recruited from the research team and close collaborators” and that the work was “conducted as part of the research project.” While this ensures domain expertise, it introduces a significant risk of confirmation bias. The manuscript lacks a discussion on how this potential bias was mitigated (e.g., blinding, independent adjudication protocols). Furthermore, the text does not mention whether an Institutional Review Board (IRB) or equivalent ethics committee reviewed this internal annotation process. Given the high stakes of training safety-critical models on this data, the authors should explicitly state the ethical oversight measures taken.
2. **Data Licensing and Proprietary Content:** The dataset TELBench is built from trajectories generated by running public benchmarks through proprietary, closed-source models (GPT-5, Claude-Sonnet-4.5, Gemini-2.5-Pro). While the *tasks* are public, the *outputs* (the trajectories) are generated by models with specific Terms of Service (ToS). The paper does not address whether the redistribution of these specific model outputs in a public benchmark (via Hugging Face) complies with the ToS of OpenAI, Anthropic, or Google. Some model providers restrict the redistribution of their raw outputs. Failure to address this could lead to the dataset being taken down, undermining the reproducibility and safety utility of the work.
3. **Definition of “Harmful”:** The paper defines an error span as one that introduces a “mistaken, unsupported, contradicted, or prematurely committed judgment.” While this is a technical definition, the term “harmful” in the abstract implies a broader safety impact. The authors should clarify if “harmful” strictly refers to factual incorrectness leading to task failure, or if it encompasses potential downstream safety risks (e.g., hallucinated medical advice, legal misinformation). If the latter, the annotation guidelines should explicitly include safety-specific criteria, which are currently absent from the provided text.

Addressing these points will strengthen the ethical robustness of the dataset and the validity of the safety claims made in the paper.

Action items.

- [writing] The ‘Annotator recruitment’ section (Appendix) notes annotators were internal team members. Explicitly address potential bias, confirm if IRB approval was sought,

and detail compensation to mitigate coercion.

- [writing] The dataset TELBench redistributes outputs from proprietary models (GPT-5, Claude, Gemini). Clarify compliance with model providers' Terms of Service regarding the redistribution of generated trajectories in a public benchmark.
- [writing] The term 'harmful' is used broadly. Clarify if this strictly means factual error or includes downstream safety risks (e.g., medical misinformation). If the latter, ensure annotation guidelines explicitly cover safety-specific criteria.

Scientific Evidence

Weights the strength of the scientific evidence: sample sizes, controls, replication, effect sizes, p-hacking risk, and robustness of the central claims to plausible alternative explanations.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_scientific_evidence.md

The paper presents a compelling shift from outcome-based to process-based evaluation for deep-research agents, but the scientific evidence supporting the robustness of the proposed benchmark (TELBench) and the framework (DRIFT) is currently insufficient due to a lack of statistical rigor and reliability metrics.

First, the experimental protocol described in `sections/experiment.tex` states that “Each setting is repeated three times.” However, the results in `tab/main_exp.tex` and `fig:performance` report only single-point estimates (means). For LLM-based evaluations, which are inherently stochastic, reporting only the mean without standard deviation, confidence intervals, or statistical significance testing (e.g., paired t-tests or bootstrap resampling) is a critical weakness. A 30 percentage point gain is substantial, but without variance estimates, it is impossible to determine if this improvement is consistent or an artifact of specific random seeds. The authors must provide error bars or statistical significance tests to validate the claim that DRIFT robustly outperforms baselines.

Second, the construction of the ground truth for TELBench relies heavily on an LLM-assisted pipeline (`sections/traj_collection.tex`). While the authors mention “two independent LLM annotators” and “two expert annotators,” they fail to report any inter-annotator agreement metrics (e.g., Cohen’s Kappa or Fleiss’ Kappa). In annotation tasks involving complex semantic judgments like “unsupported commitment” or “premature finalization,” human agreement is rarely perfect. Without reporting these agreement scores, the reliability of the gold labels is unknown. If the ground truth is noisy or inconsistent, the evaluation of DRIFT becomes unreliable, and the reported performance metrics may reflect the model’s ability to match noisy labels rather than true error localization.

Finally, the ablation study in `sections/further_analysis` and `figure/appendix_ablation_prf_four_models_pastel_20260526.pdf` attributes performance gains to specific modules (Claim Keeper, Support Seeker). The text asserts these gains are “not merely caused by over-predicting,” but lacks statistical evidence. The authors should include significance

tests comparing the full DRIFT pipeline against its ablated variants to confirm that the modular design is the actual driver of performance, rather than random fluctuation.

To strengthen the scientific evidence, the authors must: (1) report standard deviations and statistical significance for all main results and ablation studies; (2) provide inter-annotator agreement scores for the TELBench annotation process; and (3) clarify the statistical power of the three-run experimental design.

Action items.

- [science] The claim that ‘Each setting is repeated three times’ (Experiment Settings) lacks statistical rigor. For a benchmark of 1,000 instances, reporting only the mean of three runs without standard deviation, confidence intervals, or significance testing (e.g., paired t-tests or Wilcoxon signed-rank) makes it impossible to assess if the reported ~30% F1 gains are robust or due to random variance in the LLM’s stochastic sampling.
- [science] The annotation pipeline relies on ‘two independent LLM annotators’ followed by ‘two expert annotators’ (Dataset section). The paper does not report inter-annotator agreement (e.g., Cohen’s Kappa or Fleiss’ Kappa) for either the LLM stage or the human expert stage. Without these metrics, the reliability of the ground truth labels in TELBench is unverifiable, and the benchmark’s validity is questionable.
- [science] The ablation study (Figure 1c, Appendix) claims performance gains from specific modules (Claim Keeper, Support Seeker). However, the text does not specify if these ablation results are statistically significant or if the improvements are consistent across the three random seeds. A statistical test comparing the full DRIFT against the ablated variants is required to support the claim that the gains arise from the proposed modules rather than noise.

Statistical Analysis

Scrutinizes the statistics — appropriateness of tests, multiple-comparison handling, confidence intervals, model assumptions, and the reproducibility of the analyses.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_statistical_analysis.md

The statistical reporting in the experimental section requires strengthening to support the strong claims of performance improvement. While the paper provides point estimates for Precision, Recall, F1, and First-Error Accuracy (FEA) across multiple models and baselines, it lacks measures of uncertainty. The statement that “Each setting is repeated three times” (Experiment Settings, line 4) implies that variance data exists, yet the results tables (Table 1) and figures (Figure 1, Figure 2) only display single-point values. In LLM evaluation, where stochasticity can lead to significant variance, reporting only the mean without standard deviation or confidence intervals makes it difficult to assess the reliability of the reported gains (e.g., the ~30% F1 improvement).

Specifically, the claim that DRIFT “outperforms... by up to 30 percentage points” needs

statistical backing. A paired statistical test (such as a paired t-test or Wilcoxon signed-rank test) across the three runs for each model-benchmark pair should be conducted to determine if the improvements are statistically significant ($p < 0.05$). Similarly, the ablation study in Figure 2c and the appendix should include error bars or significance markers to validate that the incremental gains from specific modules are not due to chance.

Furthermore, in the mechanism analysis (Appendix, Stage-normalized error risk), the paper reports specific error rates (e.g., 60.5% for decision-making). These are proportions derived from a finite sample of spans. To rigorously support the conclusion that certain stages are “intrinsically more error-prone,” the authors should report 95% confidence intervals for these proportions. Without these intervals, the distinction between stages with similar rates (e.g., 60.5% vs. 51.8%) may not be statistically meaningful. Adding these statistical rigor elements will significantly enhance the credibility of the empirical findings.

Action items.

- [science] Report confidence intervals or standard deviations for the three repeated runs. Point estimates alone cannot validate the claimed ~30% F1 improvements as statistically significant.
- [science] Add statistical significance tests (e.g., paired t-tests) for DRIFT vs. baselines and ablation comparisons to confirm gains are not due to random variance.
- [science] Provide 95% confidence intervals for normalized error rates in the appendix (e.g., 60.5% for decision-making) to support claims about stage-specific risk.

Writing Quality

Reads the manuscript purely as prose — clarity, flow, sentence-level grammar, paragraph cohesion, and overall readability — setting the scientific content aside.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_writing_quality.md

The manuscript is generally well-written, with a clear narrative flow and precise technical vocabulary appropriate for the field. The structure effectively guides the reader from the problem definition to the proposed solution and empirical validation. However, there are several minor grammatical errors, typos, and punctuation inconsistencies that detract from the overall polish and should be addressed before final publication.

Specifically, in the Abstract, the spacing before the footnote marker for \textsc{DRIFT} is non-standard due to an unnecessary tilde. In the Introduction, under the contributions list, the word “frameworks” is misspelled as “framewrok”. In Section 4.2, there is a subject-verb agreement error where “Table... and Figure... shows” should be “show”. Additionally, the phrase “where first goes wrong” in the same section is grammatically incomplete and requires a subject (e.g., “where the error first goes wrong”). Finally, the appendix section title “Detailed Error Analysis for Deep-research Agent Systems.” includes an unnecessary terminal period, which is inconsistent with the rest of the document’s heading style.

While these issues are minor and do not obscure the scientific meaning, correcting them will significantly improve the professional quality and readability of the paper. The authors are encouraged to perform a thorough proofread to catch similar small errors throughout the text.

Action items.

- [writing] In the Abstract, there is a non-breaking space before the footnote marker for DRIFT ('DRIFT~\footnote'). Remove the tilde to ensure standard spacing.
- [writing] In Section 3 (Dataset), the phrase 'two framewrok' in the contributions list is a typo and should be 'two frameworks'.
- [writing] In Section 4.2 (Main Results), the sentence 'Table~\ref{tab:difficulty-split} and Figure~\ref{fig:performance} shows' contains a subject-verb agreement error; 'shows' should be 'show' to agree with the plural subject.
- [writing] In Section 4.2, the phrase 'where first goes wrong' is grammatically incomplete. It should be revised to 'where the error first goes wrong' or 'where things first go wrong'.
- [writing] In the Appendix, Section 'Detailed Error Analysis for Deep-research Agent Systems', the title uses a period at the end ('Systems.') which is inconsistent with standard section heading conventions and should be removed.
