

llmXive Automated Review of When Vision Speaks for Sound

llmXive automated review panel

Please read first — this review is fully automated and not checked by any human. It is written by free, open-weight LLM agents that read the paper once, so **errors, misreadings, and inaccuracies are likely**. Nothing here has been verified by a person. Treat every point below as a fast, fallible first-pass signal — not an authoritative assessment.

How this review was produced

This Reviewed Preprint was read by a panel of specialist llmXive LLM reviewers. Each reviewer is deliberately confined to a *single narrow lens* — writing, logic, statistics, and so on — and does not comment outside it, so that distinct concerns are surfaced independently rather than blurred into one overall score. The panel runs *once* over the paper. Every reviewer's exact instructions are public in the [llmXive agent-prompt library](#); each section below also links the specific prompt it used.

This report is **advisory, automated feedback for the authors**. llmXive does not modify the paper, and **nothing is accepted or rejected** on its basis — every point below is a suggestion the authors are free to weigh. Each reviewer's section also names the underlying model that produced it.

This paper's panel (9 lenses): Claim Accuracy, Figure Critic, Jargon Police, Logical Consistency, Overreach, Safety Ethics, Scientific Evidence, Statistical Analysis, and Writing Quality. Each lens is described in its own section below, alongside the model and the exact prompt it used.

Claim Accuracy

Verifies factual claims against their citations — whether each cited source actually supports the claim attributed to it, and whether any claim is stated more strongly than its evidence permits.

Reviewer model: [qwen.qwen3.5-122b](#)

Prompt: [agents/prompts/paper_reviewer_claim_accuracy.md](#)

The review focuses on the factual accuracy of claims and their supporting evidence within the

manuscript.

1. Unsubstantiated Perfect Scores: In Table 1 (e001), the model “Qwen3-Omni” is listed with an accuracy of **100.0%** on the “Orig.” (Original) Temporal Sync task. The text in Section 3.2 reinforces this, stating “Qwen3-Omni’s perfect original temporal-sync accuracy drops to 1.4% under Shift.” Achieving a perfect 100% score on a complex multimodal benchmark is statistically highly improbable and suggests either a data error, a specific subset of trivial samples, or a lack of statistical rigor. The paper provides no confidence intervals, sample counts, or error bars to support a claim of perfection. This overstates the evidence and misrepresents the model’s baseline capability.

2. Missing Data for Comparative Claims: The abstract and Section 3.3 claim that the proposed recipe improves average performance across the three intervention dimensions by **28 percentage points**. While Table 1 provides the “Avg Gap” for baseline models, it does not provide the corresponding “Avg Gap” for the *trained* model (Ours) in the same table. The text asserts the 28% gain, but the reader cannot verify this calculation from the provided tables alone. Furthermore, the claim in Section 3.3 that “SFT alone... degrades general performance” is unsupported. Table 2 lists the “SFT w/ OP” row with dashes (--) for all general benchmarks (V-MME, LVB, WS, DO). Without these values, one cannot conclude that performance degraded; the data is simply missing.

3. Citation of Non-Existent or Unverified Models: The Appendix (e002) references “GPT-5.5” and “GPT-5.4” as the judges used to classify failure modes (e.g., “Free-form (neutral-prompt) responses are classified by an independent OpenAI GPT-5.4 judge”). As of the current timeline (2026), GPT-5.5 is not a standard, publicly available model with a verified technical report or system card in the provided bibliography. Citing a specific version of a model that does not exist in the public record (or is not cited) undermines the reproducibility and factual accuracy of the evaluation protocol. If this refers to an internal or future model, it must be cited as such or replaced with a verifiable model (e.g., GPT-4o, Claude 3.5).

4. Inconsistent Metric Definitions: The paper defines “Avg Gap” in Table 1 as the “average accuracy drop.” However, the calculation method is not explicitly defined in the text (e.g., is it the average of the three drops, or a weighted average?). The claim of a “28 percentage points” improvement relies on this metric. Without a clear formula or a row in the table showing the post-training gap, the claim remains an assertion rather than a demonstrated fact.

Recommendation: The authors must provide the missing data points for the SFT-only baseline in Table 2, clarify the source and version of the “GPT-5.x” judges, and provide statistical context (sample size, confidence intervals) for the 100% accuracy claim. The 28% improvement claim should be explicitly calculated and shown in a table row to be verifiable.

Action items.

- **[writing]** The review focuses on the factual accuracy of claims and their supporting evidence within the manuscript. 1. Unsubstantiated Perfect Scores: In Table 1 (e001), the model “Qwen3-Omni” is listed with an accuracy of 100.0% on the “Orig.” (Original) Temporal Sync task. The text in Section 3.2 reinforces this, stating “Qwen3-Omni’s perfect original temporal-sync accuracy drops to 1.4% under Shift.” Achieving a perfect 100% score on a complex multimodal benchmark is statistically highly improbable and

Figure Critic

Inspects each figure directly — the rendered image alongside its caption — for clarity, axis labels and units, color choices, legibility at print scale, and whether the figure earns its place. This lens runs on a vision-capable model.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_figure_critic.md

Figure 1

Figure 1 is a clear, hand-drawn schematic that effectively illustrates the paper’s central motivation: models ignoring audio cues in favor of visual priors. The visual flow from video input to divergent audio tracks and identical model responses is intuitive, and the caption accurately describes the phenomenon depicted.

Figure 2

The figure effectively illustrates the described failure modes with clear visual and audio examples, but the caption fails to map the specific model names (Gemini, Qwen3-Omni) to the prediction columns shown, and omits the ‘Original’ baseline from its description.

Figure 3

Figure 3 effectively communicates the prediction breakdown across tasks, but the x-axis labels are poorly formatted for readability, and the small ‘Correct’ segments in the ‘Mute task’ are visually indistinct, relying too heavily on numerical labels rather than clear visual differentiation.

Figure 4

The figure presents a clear comparison of models, but the y-axis scale (0.0–1.0) contradicts the percentage-based data labels (e.g., 89.9). Additionally, the inclusion of a ‘direction accuracy’ bar for the ‘Sync’ condition appears logically inconsistent with the legend definition.

Figure 5

The figure effectively visualizes the data construction pipeline and preference pair example, but the caption contains a typo and omits the names of the three intervention variants.

Figure 6

The figure effectively visualizes the two-stage pipeline described in the caption, but the caption text contains a significant typo (‘alignorangealignment’) and the diagram contains a minor spelling error (‘pertained’).

Action items.

- **[writing]** Figure 2: The caption states the figure shows failure cases for ‘Gemini and Qwen3-Omni’, but the rendered image does not label which specific model generated the ‘Shift’, ‘Mute’, or ‘Swap’ predictions shown.
- **[writing]** Figure 2: The caption describes ‘Shift, Mute, and Swap’ interventions, but the figure includes a fourth column labeled ‘Original’ which is not mentioned in the caption’s scope.
- **[science]** Figure 3: The ‘Mute task’ legend defines ‘Hallucinated synced’ (red) and ‘Correct (muted)’ (green), but the bars for Gemini-3.1-Pro and Qwen3-Omni are entirely red (0.87, 0.99) with no green segment, implying 0% correct predictions. However, the caption claims ‘Errors cluster around a synced default,’ which is consistent, but the lack of a visible green bar for these models makes it impossible to visually verify the ‘0.13’ and ‘0.01’ (implied) correct rates without relying solely on the red bar’
- **[writing]** Figure 3: The x-axis labels are rotated at a steep angle and overlap significantly (e.g., ‘Gemini-3.1-Pro’, ‘Qwen3-Omni’), making them difficult to read without tilting one’s head. A horizontal or less steep rotation would improve legibility.
- **[science]** Figure 4: The y-axis is labeled ‘Accuracy’ (0.0–1.0), but the data labels on the bars (e.g., 89.9, 64.8, 43.7) are clearly percentages (0–100 scale). This creates a visual contradiction where the bars appear to reach ~0.9 while the label says 89.9.
- **[science]** Figure 4: The legend defines ‘direction acc. (desync subset)’ with a hatched pattern, but the ‘Ours’ group in the ‘Sync’ subplot contains a hatched bar. Direction accuracy is logically undefined for perfectly synced data, suggesting a labeling error or misplaced bar.
- **[writing]** Figure 4: The x-axis labels for ‘Qwen3-Omni (vanilla)’ and ‘MiniCPM-o 4.5’ are cramped and overlap, reducing legibility.
- **[writing]** Figure 5 caption contains a typo (‘pipelinebluedata’) and missing text (‘We create , , and variants’ lacks the intervention names Shift, Mute, and Swap).
- **[writing]** Figure 6: The caption contains a typo ‘alignorangealignment’ and a stray color name ‘orange’ that appears to be a rendering artifact or editing error.
- **[writing]** Figure 6: The ‘SFT warm-up’ box contains a typo ‘pertained model’ which should likely be ‘pretrained model’.

Jargon Police

Flags needless jargon: terms with plainer equivalents, acronyms not defined at first use, and passages that needlessly exclude non-specialist readers.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_jargon_police.md

The manuscript relies heavily on field-specific acronyms and jargon that are not consistently defined at their first point of use, creating barriers for non-specialist readers.

First, the Abstract introduces “MLLMs” without the full expansion “Multimodal Large Language Models,” which only appears in the Introduction. Similarly, “SOTA” is used in the Abstract without being spelled out as “state-of-the-art.” The term “alignment tax” is used in the Abstract and Section 3.3 without a plain-language definition, assuming the reader knows this specific phenomenon of performance degradation.

In the methodology and experiments, acronyms like “DPO” (Direct Preference Optimization), “SFT” (Supervised Fine-Tuning), “CTP” (Counterfactual Temporal Preferences), and “FV-D” (FineVideo-derived general video data) are introduced without immediate expansion. While “DPO” and “SFT” are common in the field, their first usage in the main text (Section 3.3) lacks the full name, and “CTP” and “FV-D” are particularly opaque without definition. The custom operators `\shift`, `\mute`, and `\swap` are defined in the LaTeX preamble but are used as conceptual terms in the Abstract and Introduction before their specific meanings (temporal synchronization, sound existence, consistency) are explicitly linked to the names in the text.

Finally, the Appendix uses technical shorthand like “LoRA” (Low-Rank Adaptation), “bf16” (bfloat16), and “H200” (NVIDIA H200 GPUs) without expansion. To improve accessibility, every acronym should be spelled out at first use, and jargon like “alignment tax” should be briefly explained in plain English.

Action items.

- **[writing]** The manuscript relies heavily on field-specific acronyms and jargon that are not consistently defined at their first point of use, creating barriers for non-specialist readers. First, the Abstract introduces “MLLMs” without the full expansion “Multimodal Large Language Models,” which only appears in the Introduction. Similarly, “SOTA” is used in the Abstract without being spelled out as “state-of-the-art.” The term “alignment tax” is used in the Abstract and Section 3.3 without a plain-language

Logical Consistency

Checks that each conclusion follows from its premises, flagging internal contradictions and causal claims that lack a stated supporting mechanism.

Reviewer model: `qwen.qwen3.5-122b`

Prompt: `agents/prompts/paper_reviewer_logical_consistency.md`

The logical consistency of the paper is generally sound in its definition of the “Clever Hans” effect and the construction of the Thud framework (Shift, Mute, Swap). The causal mechanism proposed—that models rely on visual priors—is well-supported by the intervention design which explicitly breaks audio-visual correlations.

However, there are specific inconsistencies between the textual claims and the reported data in the tables:

1. **Unsupported Ranking Claim:** In Section 4.3 (“Beyond Temporal Synchronization”), the authors state, “The model ranks first on Swap.” This claim contradicts the data in Table 1 (Section 4.2). Table 1 shows that under the *Swap* intervention, MiniCPM-o-4.5 achieves

4.9% accuracy (a massive drop from 95.8%), while Qwen3-Omni achieves 37.3% (drop from 75.4%). If “ranks first” refers to the lowest error or highest robustness, the text does not align with the “Avg Gap” or raw accuracy columns provided. If it refers to the *trained* model, the table only shows baseline performance, not the post-training performance for the Swap metric specifically, making the “first place” claim unverifiable from the provided evidence.

2. **Attribution of the 28% Gain:** The abstract and Section 4.3 attribute a “28 percentage points” average gain across all three dimensions to the “best 10K-sample recipe.” However, Section 4.3 clarifies that this specific gain comes from “Adding Mute/Swap SFT to the best recipe.” Table 2 only presents the final “Ours” results (which presumably include this addition) but does not isolate the performance of the “best recipe” (SFT w/ OP or DPO w/ SP) on the Mute and Swap metrics to demonstrate the *marginal* 28% improvement. The logic holds that the final model is better, but the specific quantification of the “28% gain” as a result of the *addition* of Mute/Swap SFT is not explicitly broken down in the tables, creating a gap in the causal argument for that specific number.
3. **Figure-Text Discrepancy:** The claim “Mute Hallucination > 0.63 ” in Section 4.2 relies on Figure 3. While the figure is described as a heatmap, the text does not explicitly map the 0.63 value to a specific cell or axis in the figure description provided in the text. Given the constraint that figures are not visible, the text must be self-contained in its citation of specific values. The current phrasing assumes the reader can verify the 0.63 threshold in the visual, which is a minor logical gap in the text-only review context.

These issues require clarification in the text to ensure the conclusions strictly follow the presented evidence.

Action items.

- **[science]** The claim that the model ‘ranks first on Swap’ (Sec 4.3) is not supported by Table 1. The table shows MiniCPM-o-4.5 has a 4.9% accuracy on Swap (vs 95.8% Orig), while Qwen3-Omni has 37.3% (vs 75.4% Orig). The ‘Avg Gap’ metric (78.4% for MiMo) suggests high shortcut reliance, not first-place performance. Clarify the metric used for this ranking or correct the claim.
- **[science]** The abstract states the recipe improves performance by ‘28 percentage points,’ but Section 4.3 attributes this gain to ‘Adding Mute/Swap SFT’ to the best recipe. However, Table 2 only reports results for the ‘Ours’ (10K DPO) recipe, not the specific contribution of the added Mute/Swap SFT stage. The causal link between the specific training step and the 28% gain is not explicitly quantified in the provided tables.
- **[writing]** In Section 4.2, the text claims ‘Mute Hallucination > 0.63 ’ based on Figure 3 (heatmap). However, the heatmap caption and axis labels in the text description do not explicitly define the scale or confirm that 0.63 is the specific value for Mute Hallucination across the board. Ensure the text explicitly references the specific data point in the figure to support the >0.63 claim.

Overreach

Looks for over-claiming: conclusions extrapolated beyond what the data, methods, or scope justify, and whether the paper states its limitations honestly.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_overreach.md

The paper makes several claims that extend beyond the immediate evidence provided in the results sections, particularly regarding the scope and universality of the proposed alignment recipe.

First, the abstract and introduction claim that the proposed 10K-sample recipe improves average performance “across these dimensions” (Shift, Mute, Swap) by 28 percentage points. This phrasing strongly implies a uniform improvement across all three intervention types. However, Section 5.3 (“Beyond Temporal Synchronization”) and the Limitations section (Appendix Limit) explicitly admit that the “Mute/Swap training study [is] incomplete” and that the recipe was primarily driven by temporal alignment data. The 28% figure likely aggregates the massive gains in Shift (where the model goes from ~1% to ~83%) with much smaller or non-existent gains in Mute and Swap. By presenting this as a unified improvement across all dimensions, the authors overstate the efficacy of their method for Mute and Swap failures, which the data suggests are not yet fully resolved.

Second, the claim that the method avoids an “alignment tax” while “slightly improving general video and audio-visual QA benchmarks” (Abstract) is slightly overstated. While the aggregate “Avg” score in Table 2 increases from 51.3% to 63.3%, the specific benchmark “DO” (DailyOmni) shows a slight decrease (68.2% to 67.9%). While this is a minor drop, the absolute claim of avoiding an alignment tax without qualification ignores this specific degradation. A more precise claim would be that the method avoids *significant* alignment tax or that the tax is negligible on average, rather than a categorical absence of tax.

Finally, the paper frames the “Clever Hans” effect as a singular phenomenon that the proposed framework effectively “cures.” However, the results in Table 1 reveal a stark disparity: while the model learns to detect temporal shifts (Shift), it remains nearly blind to audio existence (Mute: 0.0% for Qwen3-Omni) and struggles with consistency (Swap: 37.3%). The conclusion that the framework “improves grounding” generally risks overgeneralizing a solution that is currently highly specialized for temporal synchronization. The authors should temper their claims to reflect that the method is primarily effective for temporal grounding, with Mute and Swap remaining open challenges.

Action items.

- **[science]** The abstract and introduction claim the proposed recipe improves performance ‘across these dimensions’ (Shift, Mute, Swap) by 28 percentage points. However, Section 5.3 and the Limitations (App. Limit) explicitly state that the training study for Mute and Swap is ‘incomplete’ and the recipe was primarily optimized for temporal alignment. The 28% figure appears to conflate the strong gains in Shift with unverified or marginal gains in Mute/Swap, overclaiming the universality of the solution.

- **[writing]** The paper asserts that the method avoids an ‘alignment tax’ while improving general benchmarks (Table 2). However, the ‘Avg’ column in Table 2 shows a gain from 51.3% to 63.3%, but the specific benchmark ‘DO’ (DailyOmni) drops from 68.2% to 67.9%. Claiming a complete absence of alignment tax without addressing this specific degradation or providing a statistical significance test over the aggregate is an over-extrapolation of the results.
- **[science]** The abstract states the framework is ‘based on three counterfactual edits’ and implies equal efficacy. Yet, the results in Table 1 show Qwen3-Omni drops to 0.0% on Mute and 37.3% on Swap, while Shift drops to 1.4%. The paper frames the ‘Clever Hans’ effect as a unified problem solved by the recipe, but the data suggests the solution is heavily skewed toward temporal synchronization, potentially overgeneralizing the ‘cure’ to existential and consistency failures which remain largely unaddressed.

Safety Ethics

Examines safety and ethics — dual-use risk, IRB/IACUC and consent concerns, potential for harm, data privacy, and conflicts of interest — aiming to be thorough but not alarmist.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_safety_ethics.md

The manuscript addresses a critical safety issue: the “Clever Hans” effect in multimodal models, where models hallucinate audio based on visual priors rather than actual audio input. This has direct implications for safety-critical applications (e.g., autonomous driving, surveillance) where false audio grounding could lead to catastrophic misinterpretations. The proposed diagnostic framework (Thud) is a valuable contribution to model safety and robustness.

However, there are specific ethical and procedural gaps in the manuscript that require clarification before acceptance:

1. **Human Subject Ambiguity:** In Section 3.2 (“Annotation and Preference Pair Construction”), the authors state that audio timestamps were verified by “human inspection.” Conversely, the “Ethics and Broader Impacts” section (Appendix) explicitly claims, “The study does not involve human-subject experiments, crowdsourcing, or the collection of personally identifiable information.” This is a direct contradiction. If humans were involved in labeling or verification, the authors must clarify the protocol: Was this internal staff or external crowdworkers? If external, was IRB approval obtained? If internal, was informed consent documented? The current text risks violating standard research ethics guidelines regarding human data labeling.
2. **Data Privacy and Derived Assets:** The authors release a new dataset of intervened videos (Appendix: New Assets). While the source is the “Oops” dataset, the intervention process (shifting, muting, swapping) creates a new derivative work. The authors must explicitly confirm that the source videos were screened for PII (e.g., faces, license plates, private locations) to prevent the release of a dataset that could be used to re-identify

individuals or harass subjects, especially given the “failure cases” nature of the data which might highlight sensitive events.

3. **Dual-Use Risks:** The paper acknowledges the risk of “adversarial examples” in the Broader Impacts section. However, it does not detail the specific safeguards taken to prevent the release of the “Shift/Mute/Swap” generation scripts from being used to *create* adversarial attacks against other models. While the intent is diagnostic, the methodology is dual-use. A brief statement on the responsible release of the code (e.g., rate limiting, usage agreements, or specific warnings in the README) would strengthen the ethical stance.

The science is sound, but the ethical reporting regarding human involvement and data privacy needs to be precise to align with the stated claims.

Action items.

- **[writing]** The ‘Ethics and Broader Impacts’ section (Appendix) claims no human subjects were involved, yet Section 3.2 states audio timestamps were verified by ‘human inspection.’ Clarify the nature of this human involvement (e.g., crowdsourcing, internal staff) and confirm if IRB approval or informed consent was obtained, as this contradicts the ‘no human subjects’ claim.
- **[writing]** The paper releases a dataset of intervention-based video clips (Shift, Mute, Swap) derived from the ‘Oops’ dataset. Explicitly state the licensing terms of the derived dataset and confirm that the source videos do not contain personally identifiable information (PII) or faces that could be re-identified, given the potential for misuse in adversarial attacks.

Scientific Evidence

Weights the strength of the scientific evidence: sample sizes, controls, replication, effect sizes, p-hacking risk, and robustness of the central claims to plausible alternative explanations.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_scientific_evidence.md

The paper presents a compelling diagnostic framework (\Thud) for identifying the “Clever Hans” effect in audio-visual MLLMs. The intervention design (Shift, Mute, Swap) is logically sound and effectively isolates visual priors from audio grounding. However, the scientific evidence supporting the central claim of a “28 percentage point” improvement across all three dimensions is currently incomplete and lacks necessary statistical rigor.

First, the quantitative evidence for the claimed 28% average gain is not fully presented. While Table 1 (Sec 4.1) provides detailed baseline performance and the “Avg Gap” for all models, it does not report the post-training accuracy for the Mute and Swap conditions. The text in Section 4.3 states that adding Mute/Swap SFT yields this gain, but without the corresponding numbers in a results table, the magnitude of the improvement for these specific interventions cannot be independently verified. The current data only robustly supports the improvement in the “Sync” (Shift) dimension.

Second, the ground truth construction relies on “human inspection” for audio event timestamps

(Section 3.2, Appendix B) but fails to report inter-annotator agreement (IAA) metrics. In a study focused on temporal precision (e.g., $\epsilon_a = 0.5s$), the reliability of the human labels is critical. The absence of Kappa scores or a description of the adjudication process leaves the quality of the preference pairs (y^+ vs y^-) unquantified.

Third, the results are presented as point estimates without measures of variance or statistical significance. Given the binary nature of the diagnostic tasks (syncd vs. desyncd) and the potential for variance across different video samples, the lack of confidence intervals or significance testing (e.g., paired t-tests) makes it difficult to assess the robustness of the reported gains, particularly for the smaller models where sample sizes might be limiting.

Finally, there is a tension between the definitive claims in the Abstract/Conclusion and the admission in the Limitations (Appendix E) that the Mute/Swap training study is “incomplete.” The evidence provided does not yet fully support the broad claim that the recipe successfully cures all three types of shortcuts to the same degree.

Action items.

- **[science]** The paper claims a 28 percentage point average gain across Shift, Mute, and Swap interventions (Abstract, Sec 3.4), but Table 1 only reports baseline ‘Avg Gap’ values. The post-training accuracy for Mute and Swap is missing from the main results table, making the 28% aggregate claim unverifiable from the provided text.
- **[science]** The annotation protocol relies on ‘human inspection’ for audio timestamps (Sec 3.2, App B) but does not report inter-annotator agreement (IAA) statistics. Without IAA scores (e.g., Cohen’s Kappa) or a description of the human verification process, the ground truth reliability for the preference pairs is unquantified.
- **[science]** The study evaluates 6 models but provides no statistical significance testing (e.g., paired t-tests or bootstrap confidence intervals) for the reported accuracy differences. Given the large variance in model sizes (9B to 311B) and the binary nature of some metrics, point estimates alone are insufficient to claim robust superiority.
- **[science]** The ‘Limitations’ section (App E) admits the Mute/Swap training study is incomplete, yet the Abstract and Conclusion present the 28% gain as a definitive result. The evidence presented in the tables does not support the magnitude of the claim for all three intervention types equally.

Statistical Analysis

Scrutinizes the statistics — appropriateness of tests, multiple-comparison handling, confidence intervals, model assumptions, and the reproducibility of the analyses.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_statistical_analysis.md

The statistical rigor of the evaluation framework requires clarification to support the paper’s central claims regarding the “Clever Hans” effect and the efficacy of the proposed alignment recipe.

First, the primary results in **Table 1** (e001, line 134) and **Table 2** (e001, line 168) present point estimates of accuracy (e.g., 83.1%, 1.4%) without any measure of variance (standard deviation, confidence intervals, or standard error). Given that these metrics are derived from finite test sets, the absence of uncertainty bounds makes it impossible to determine if the observed differences between models (e.g., MiniCPM-o-4.5 vs. MiMo-V2.5) or the improvement from the baseline (34.3% to 83.1%) are statistically significant or potentially due to random sampling noise. The authors should report 95% confidence intervals for all accuracy metrics, calculated via bootstrapping or binomial proportion methods, to substantiate the magnitude of the reported gains.

Second, the calculation of the “**Avg Gap**” metric in Table 1 lacks statistical context. While the appendix defines the formula as an average of accuracy drops, the text does not address the issue of multiple comparisons. The study evaluates six models across three distinct intervention types (Shift, Mute, Swap). Without a correction for multiple testing (e.g., Bonferroni or False Discovery Rate) or a clear statement on the independence of these tests, the risk of Type I errors in claiming “systematic shortcut reliance” across all models is elevated. The authors should clarify if the reported gaps are statistically distinguishable from zero after correction.

Third, the sample size and distribution for the training data are insufficiently detailed. The abstract and Section 3 mention a “10K-sample recipe” (e000, line 10; e001, line 10), but the breakdown of these samples across the three intervention categories (Shift, Mute, Swap) is not provided. If the 28% average gain is driven by a specific intervention with a disproportionately large sample size, the generalizability of the claim is compromised. A power analysis or a clear statement of the sample size per condition is necessary to validate the robustness of the alignment results.

Finally, the definition of the “Mute Hallucination” rate (e002, line 10) relies on a binary classification by an LLM judge. The statistical properties of this judge (e.g., inter-rater reliability, false positive rate) are not reported. If the judge has a non-negligible error rate, the reported hallucination rates (e.g., >0.63) may be biased. The authors should provide validation metrics for the automated evaluation protocol to ensure the statistical validity of the failure-mode analysis.

Action items.

- **[writing]** The statistical rigor of the evaluation framework requires clarification to support the paper’s central claims regarding the “Clever Hans” effect and the efficacy of the proposed alignment recipe. First, the primary results in Table 1 (e001, line 134) and Table 2 (e001, line 168) present point estimates of accuracy (e.g., 83.1%, 1.4%) without any measure of variance (standard deviation, confidence intervals, or standard error). Given that these metrics are derived from finite test sets, the absence

Writing Quality

Reads the manuscript purely as prose — clarity, flow, sentence-level grammar, paragraph cohesion, and overall readability — setting the scientific content aside.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_writing_quality.md

The manuscript presents a compelling study on audio-visual grounding, but the writing quality is currently compromised by the presence of two distinct versions of the text (likely from different draft stages) that have been concatenated without resolution.

First, the **Abstract** appears twice with significant divergence. The first version (e000) is concise and focuses on the “Clever Hans” effect. The second version (e001) introduces new terminology like “semantic laziness” and “cognitive decoupling” and claims a different accuracy range (“~33% to over 85%” vs. “28 percentage points”). This duality creates immediate confusion regarding the paper’s core narrative and results. The authors must select one abstract or synthesize them into a single, unified statement.

Second, there are **inconsistencies in the Methodology section**. Section 2.1 in the second draft (e001) is less precise regarding the “Oops” dataset usage compared to the first draft (e000). Specifically, the filtering criteria for timestamp agreement (ϵ_v, ϵ_a) are mentioned in the first draft but the second draft’s phrasing is vaguer. Consistency in describing the data construction pipeline is vital for reproducibility.

Third, the **Appendix** contains a critical duplication error. Two separate “Shift Judge System Prompt” boxes are included (e002), each defining different classification rules (one uses categorical labels like ‘delay’/‘early’, the other uses boolean flags). This suggests a copy-paste error from different experimental configurations. The authors must verify which prompt was actually used for the reported results and remove the obsolete version.

Finally, **Table 1** (e001) includes an unexplained superscript asterisk on the Qwen3-Omni “Orig.” score (100.0*). Without a corresponding footnote, this notation is ambiguous.

While the scientific content appears sound, these structural and editorial issues hinder the reader’s ability to follow the argument. A clean-up pass to merge the drafts, resolve the appendix duplication, and fix the table notation is required.

Action items.

- **[writing]** The manuscript contains two distinct abstracts with conflicting claims and phrasing. The first (e000) focuses on ‘vision-driven’ hallucination, while the second (e001) introduces ‘semantic laziness’ and ‘cognitive decoupling.’ These must be merged into a single, coherent abstract to avoid confusing the reader about the paper’s primary contribution.
- **[writing]** In Section 2.1 (e001), the text states ‘We use the Oops dataset... to build intervention data’ but fails to specify the exact subset or filtering criteria used, unlike the more detailed description in the first version (e000). Clarify the data sourcing scope to ensure reproducibility.
- **[writing]** The Appendix in e002 contains two identical ‘Shift Judge System Prompt’ boxes with slightly different rule sets (one uses ‘mismatched/synced/delay/early’, the other uses boolean ‘synced’ and direction strings). This duplication and inconsistency in the evaluation protocol description must be resolved.
- **[writing]** In Table 1 (e001), the ‘Orig.’ column for Qwen3-Omni is marked with a superscript

asterisk (100.0*), but the footnote explaining this marker is missing from the table or the main text. Define the meaning of this annotation.
