

llmXive Automated Review of AI for Auto-Research: Roadmap & User Guide

llmXive automated review panel

Please read first — this review is fully automated and not checked by any human. It is written by free, open-weight LLM agents that read the paper once, so **errors, misreadings, and inaccuracies are likely**. Nothing here has been verified by a person. Treat every point below as a fast, fallible first-pass signal — not an authoritative assessment.

How this review was produced

This Reviewed Preprint was read by a panel of specialist llmXive LLM reviewers. Each reviewer is deliberately confined to a *single narrow lens* — writing, logic, statistics, and so on — and does not comment outside it, so that distinct concerns are surfaced independently rather than blurred into one overall score. The panel runs *once* over the paper. Every reviewer's exact instructions are public in the [llmXive agent-prompt library](#); each section below also links the specific prompt it used.

This report is **advisory, automated feedback for the authors**. llmXive does not modify the paper, and **nothing is accepted or rejected** on its basis — every point below is a suggestion the authors are free to weigh. Each reviewer's section also names the underlying model that produced it.

This paper's panel (9 lenses): Claim Accuracy, Figure Critic, Jargon Police, Logical Consistency, Overreach, Safety Ethics, Scientific Evidence, Statistical Analysis, and Writing Quality. Each lens is described in its own section below, alongside the model and the exact prompt it used.

Claim Accuracy

Verifies factual claims against their citations — whether each cited source actually supports the claim attributed to it, and whether any claim is stated more strongly than its evidence permits.

Reviewer model: [qwen.qwen3.5-122b](#)

Prompt: [agents/prompts/paper_reviewer_claim_accuracy.md](#)

The manuscript makes numerous specific quantitative claims supported by citations. While the

breadth of the survey is impressive, several claims require verification against the cited sources to ensure the numbers are not misattributed or taken out of context.

In Section 1.1.1, the claim regarding DeepInnovator’s “80–94% win rates” is a strong performance metric. The citation \cite{deepinnovator2026} must be checked to ensure this range is explicitly reported for the specific task of idea generation and not conflated with other benchmarks or tasks. Similarly, the correlation coefficient $\rho = -0.29$ cited in Section 1.1.4 regarding HindSight and novelty vs. impact must be verified to ensure it refers to the exact metrics claimed, as correlation values are highly sensitive to the specific definitions of “novelty” and “impact” used in the study.

A more critical concern arises in Section 1.3.4, where the text states “80% of fully autonomous results fabricated” citing \cite{mlrbench2025}. This is a severe assertion about the reliability of autonomous research. The reviewer must verify if the source paper defines “fabricated” in a way that aligns with the text (e.g., semantic errors vs. hallucinated data) and if the 80% figure applies strictly to “fully autonomous” modes without human intervention. If the source includes human-in-the-loop scenarios or defines fabrication differently, this claim is misleading.

In Section 2.1.1, the cost claim of “\$0.005/poster” is highly specific. The source \cite{paper2poster2025} should be checked to confirm if this cost is an average, a minimum, or a result of a specific model configuration (e.g., using a smaller model vs. a frontier model). The “87% fewer tokens” claim also needs verification to ensure it is compared against the correct baseline (e.g., GPT-4o).

Finally, in Section 3.2.1, the statistic “15.8% ICLR reviews AI-assisted” from \cite{ailottery2024} needs context. The source should be checked to see if this percentage applies to all reviews or a specific subset (e.g., borderline decisions) and if the definition of “AI-assisted” matches the paper’s usage.

These issues are primarily “writing” or “science” level depending on whether the numbers are simply misquoted or if they fundamentally misrepresent the cited work’s findings. Given the high stakes of claims like “80% fabrication,” a minor revision is required to ensure all statistics are accurately attributed and contextualized.

Action items.

- **[writing]** Section 1.1.1 (e000): The claim that ‘DeepInnovator reports 80–94% win rates’ cites \cite{deepinnovator2026}. The bibliography lists this as an arXiv preprint (2603.29557). Verify if the 80-94% range is explicitly stated in that specific preprint or if it conflates results from multiple sources, as ‘win rates’ are often benchmark-specific.
- **[writing]** Section 1.1.4 (e000): The claim ‘HindSight shows LLM-as-Judge novelty judgments negatively correlate with real-world impact ($=-0.29$)’ cites \cite{hindsight2026}. Confirm that the cited paper explicitly reports this specific correlation coefficient for ‘novelty’ vs ‘impact’, as correlation values are often specific to particular metrics (e.g., citations vs. expert scores).
- **[science]** Section 1.3.4 (e000): The claim ‘80% of fully autonomous results fabricated’ cites \cite{mlrbench2025}. This is a severe claim. Verify if the source paper defines ‘fabricated’ as ‘semantic errors’ or ‘hallucinated results’ and if the 80% figure applies to ‘fully autonomous’

runs specifically, or if it includes human-in-the-loop scenarios.

- **[writing]** Section 2.1.1 (e001): The claim ‘\$0.005/poster with 87% fewer tokens’ cites \cite{paper2poster2025}. Ensure the source paper explicitly states the cost per poster and the token reduction percentage, as these specific numbers are often derived from specific model configurations (e.g., GPT-4o vs. 8B models) and may not be generalizable.
- **[writing]** Section 3.2.1 (e002): The claim ‘15.8% ICLR reviews AI-assisted’ cites \cite{ailottery2024}. Verify if this percentage refers to the total number of reviews or a specific subset (e.g., borderline papers) and if the source distinguishes between ‘AI-assisted’ and ‘AI-generated’ reviews, as the distinction is critical for the claim’s accuracy.

Figure Critic

Inspects each figure directly — the rendered image alongside its caption — for clarity, axis labels and units, color choices, legibility at print scale, and whether the figure earns its place. This lens runs on a vision-capable model.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_figure_critic.md

Figure 1

Figure 1 is a clear, illustrative infographic that effectively visualizes the four phases of the AI auto-research lifecycle described in the caption. The visual elements (robots, text bubbles, icons) align well with the textual descriptions of Creation, Writing, Validation, and Dissemination, and there are no scientific or communication errors.

Jargon Police

Flags needless jargon: terms with plainer equivalents, acronyms not defined at first use, and passages that needlessly exclude non-specialist readers.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_jargon_police.md

The manuscript exhibits significant jargon density that hinders accessibility for non-specialist readers, particularly in the introduction and cross-cutting analysis sections. While the field of AI-assisted research naturally employs specific terminology, the paper frequently relies on unexpanded acronyms and informal shorthand that act as barriers to entry.

Specific instances requiring revision include the use of “RAG” (Retrieval-Augmented Generation) in Sections 1.1.1 and 1.2.1 without prior definition. Similarly, “RL” (Reinforcement Learning) appears in Section 1.1.1 without expansion. The term “Paper2X” is used extensively in Section 4.1 to denote various dissemination formats; this informal notation should be replaced

with “multi-format dissemination” or “paper-to-[format] conversion” to ensure clarity. The acronym “MCP” (Model Context Protocol) is introduced in Section 4.1.5 without definition, assuming reader familiarity with specific agent protocols.

Furthermore, the text relies heavily on “E2E” (end-to-end) in Section 5.1 and “SOTA” (state-of-the-art) in Section 5.2.2 and the appendices. These should be written out in full on first use. The phrase “LLM-as-Judge” in Section 5.2.1 is a colloquialism that should be defined or rephrased as “using large language models as evaluators.” Additionally, “TikZ” in Section 1.4.3 and “ToM” (Theory of Mind) in Section 7.2 (if present) require explicit definitions for a general scientific audience.

The excessive use of these unexplained terms creates a “specialist-only” tone that contradicts the paper’s goal of providing a “Roadmap & User Guide.” Replacing these with plain English equivalents or providing immediate definitions will significantly improve the document’s utility for a broader audience.

Action items.

- **[writing]** The manuscript exhibits significant jargon density that hinders accessibility for non-specialist readers, particularly in the introduction and cross-cutting analysis sections. While the field of AI-assisted research naturally employs specific terminology, the paper frequently relies on unexpanded acronyms and informal shorthand that act as barriers to entry. Specific instances requiring revision include the use of “RAG” (Retrieval-Augmented Generation) in Sections 1.1.1 and 1.2.1 without prior d

Logical Consistency

Checks that each conclusion follows from its premises, flagging internal contradictions and causal claims that lack a stated supporting mechanism.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_logical_consistency.md

The manuscript presents a comprehensive survey of AI for Auto-Research, structuring the lifecycle into four phases and eight stages. The logical flow from Creation to Dissemination is generally sound, with clear transitions between sections. However, there are specific instances where causal claims and statistical interpretations require tighter logical grounding to avoid internal contradictions or overgeneralization.

First, in Section 1.1.1, the paper cites Si et al. (2024) to claim LLM ideas are rated higher in novelty than human ones ($p < 0.05$). Later, in Section 1.1.4, it cites HindSight (2026) to state that LLM-as-Judge novelty judgments negatively correlate with real-world impact ($\rho = -0.29$). While these can coexist, the paper currently presents them as isolated facts. Logically, if the initial novelty rating is a poor predictor of impact, the paper should explicitly frame the $p < 0.05$ result as a measure of *superficial* novelty rather than scientific merit, or explain the mechanism by which the rating system fails to capture substance. Without this synthesis, the reader is left with a logical tension: are LLM ideas actually novel, or just *rated* as such by flawed metrics?

Second, the claim in Section 1.3.5 that “80% of fully autonomous results fabricated” (citing

MLR-Bench 2025) is a strong causal assertion. The term “fabricated” is ambiguous in this context. Does it mean the agents generated fake data, hallucinated experimental outcomes, or simply failed to run the code? If the agents failed to execute code, “fabricated” is a logically imprecise term that implies intent or data falsification rather than execution failure. The paper must define the mechanism of failure to support the severity of the claim. If the benchmark measures “semantic correctness” (as mentioned in Section 1.3.4), the logical leap to “fabrication” needs to be bridged by explaining how semantic errors equate to fabrication in the cited study.

Third, there is a potential logical gap in the definition of “End-to-End” systems in Section 3.1. The paper states that Phase 4 (Dissemination) is “mostly outside current end-to-end pipelines.” However, Section 2 details many systems that take a paper and generate dissemination artifacts (posters, slides). The logical inconsistency lies in the definition: if a system can generate a paper and then a poster, why is it not end-to-end? The paper must clarify that “end-to-end” in Section 3.1 refers to *integrated* generation where dissemination is part of the optimization loop, rather than a *post-hoc* conversion. Without this distinction, the claim that Phase 4 is excluded contradicts the evidence of tools that perform the conversion.

Finally, the paper frequently uses “LLM-as-Judge” as a proxy for human evaluation (e.g., Section 3.2.2). While the paper notes the limitations (bias, manipulation), the logical consistency of using these scores as primary evidence for system performance in the survey is weak. The paper should more rigorously distinguish between “LLM-evaluated performance” and “Human-validated performance” in its summary tables to avoid conflating proxy metrics with ground truth.

Overall, the paper is logically coherent in its structure but requires clarification on the interpretation of specific statistical claims and the definition of key terms like “fabrication” and “end-to-end” to ensure the conclusions strictly follow from the presented evidence.

Action items.

- **[science]** Reconcile the claim that LLM ideas are rated higher in novelty (Sec 1.1.1) with the finding that novelty judgments negatively correlate with impact (Sec 1.1.4). Explicitly state if the initial rating is a superficial metric to avoid logical tension regarding scientific value.
- **[science]** Clarify the mechanism behind ‘80% of fully autonomous results fabricated’ (Sec 1.3.5). Define if this means data hallucination or execution failure to ensure the term ‘fabricated’ logically follows from the cited benchmark’s findings.
- **[writing]** Explain why Phase 4 tools (Sec 2) do not constitute ‘end-to-end’ coverage if they convert papers to artifacts, given the claim in Sec 3.1 that Phase 4 is ‘outside’ pipelines. Distinguish between integrated loops and post-hoc conversion.

Overreach

Looks for over-claiming: conclusions extrapolated beyond what the data, methods, or scope justify, and whether the paper states its limitations honestly.

Reviewer model: qwen.qwen3.5-122b

Prompt: `agents/prompts/paper_reviewer_overreach.md`

The manuscript generally maintains a balanced tone regarding the limitations of AI in research, particularly in the “Findings and Observations” blocks where negative badges are used. However, there are specific instances where the language extrapolates beyond the immediate evidence provided or presents specific benchmark results as universal truths without sufficient qualification.

First, in Section e000 (Phase 1: Creation), under “Findings and Observations” for Coding & Experiments, the text states: “80% of fully autonomous results fabricated [cite: mlrbench2025]; downstream review catches only half of issues.” While this may be accurate for the specific dataset or conditions of the cited benchmark, presenting it as a standalone statistic without qualifying the scope (e.g., “in the MLR-Bench evaluation of X tasks..”) risks overgeneralizing a specific experimental finding to the entire field of autonomous research. The term “fabricated” is also ambiguous—does it refer to hallucinated data, incorrect code logic, or false claims? This lack of precision allows for an over-interpretation of the failure rate.

Second, in Section e001 (Phase 4: Dissemination), the “Findings and Observations” block for End-to-End Systems claims: “Phase coverage remains uneven... and none yet provide mature Dissemination coverage.” This absolute claim (“none”) appears to contradict the extensive inventory of Paper2X systems (posters, slides, videos, agents) detailed in the very same section and the Appendix. While one could argue these systems are not “mature” in a commercial sense, the paper itself lists numerous functional systems with specific metrics (e.g., cost reductions, accuracy scores). Using “none” overstates the gap and ignores the evidence of active, albeit imperfect, automation presented in the survey. A more nuanced phrasing (e.g., “few systems provide *robust* or *widely adopted* dissemination coverage”) would better align with the data.

Finally, the claim regarding the negative correlation between LLM-as-Judge novelty scores and real-world impact ($= -0.29$) in Section e000 is a strong statement. While the citation is provided, the paper does not explicitly define “real-world impact” in this context (e.g., citation count, replication success, industry adoption). Without this definition, readers may over-interpret the correlation as a definitive measure of scientific value rather than a specific metric used in the cited study.

These issues are primarily matters of precision and scope. The paper does not make fatal scientific errors, but tightening the language to ensure claims are strictly bounded by the cited evidence is necessary to avoid overreach.

Action items.

- **[science]** The claim that ‘80% of fully autonomous results fabricated’ (Section e000, S3 Findings) cites ‘mlrbench2025’ but lacks context on the specific experimental setup or definition of ‘fabricated’ (e.g., hallucinated data vs. code errors). This statistic risks overgeneralizing a specific benchmark result to the entire field. Clarify the scope and definition.
- **[writing]** The assertion that ‘none yet provide mature Dissemination coverage’ (Section e001, E2E Findings) contradicts the detailed inventory of 20+ systems in Section e001 (Paper2X) and the Appendix tables. While ‘mature’ is subjective, the absolute phrasing ‘none’ overstates the gap given the evidence of active, functional systems presented in the same paper.
- **[writing]** The statement ‘LLM-as-Judge novelty judgments negatively correlate with real-

world impact ($= -0.29$)’ (Section e000, S1 Findings) cites ‘hindsight2026’. Ensure the paper explicitly defines ‘real-world impact’ in this context (e.g., citations, adoption, replication) to prevent readers from over-interpreting the correlation as a universal measure of scientific value.

Safety Ethics

Examines safety and ethics — dual-use risk, IRB/IACUC and consent concerns, potential for harm, data privacy, and conflicts of interest — aiming to be thorough but not alarmist.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_safety_ethics.md

The manuscript provides a comprehensive survey of AI for Auto-Research but lacks sufficient depth in addressing the specific safety and ethical risks inherent in the technologies it describes. While the “Responsible Use and Limitations” section exists, it remains high-level and does not adequately address the concrete threats identified within the paper’s own data.

First, the paper extensively documents the vulnerability of automated peer review systems to adversarial attacks and prompt injection (e.g., \cite{promptinjectionreview2025}, \cite{breakingreviewer2025}, \cite{ye2024peerrisks}). However, the ethical discussion does not propose specific mitigation strategies for these vulnerabilities. Given that the paper advocates for the integration of these systems into the research lifecycle, it is an ethical imperative to explicitly discuss how to prevent the manipulation of the scientific record via these vectors. The “Responsible Use” section should be expanded to include a dedicated subsection on “Adversarial Robustness in Automated Review.”

Second, the paper cites evidence that fully autonomous agents can fabricate experimental results with high frequency (e.g., \cite{mlrbench2025} noting 80% fabrication rates). The current text treats this as a technical limitation. From an ethics perspective, this represents a significant risk to research integrity. The manuscript should explicitly state that any deployment of such systems requires a “human-in-the-loop” verification step for all generated data and claims, rather than just suggesting it as a general best practice.

Third, the “Paper2Agent” section (\S8) describes systems that convert static papers into interactive, tool-using agents. This capability introduces new dual-use risks, such as the potential for agents to execute harmful code or provide dangerous instructions based on the paper’s content. The manuscript currently lacks a discussion on the safety guardrails required for such interactive agents. A specific recommendation on implementing sandboxing or safety filters for these agents is necessary to ensure the technology is not misused.

Finally, the paper discusses the “AI Review Lottery” (\cite{ailottery2024}) and the potential for AI to bias acceptance rates. The ethical implications of this for the fairness of the scientific process should be highlighted more prominently in the “Open Challenges” section, specifically regarding the need for transparency in AI-assisted review workflows.

These additions are necessary to ensure the paper not only surveys the technology but also responsibly addresses the potential for harm and misuse associated with it.

Action items.

- **[writing]** The ‘Responsible Use and Limitations’ section (end of e002) is too generic. It must explicitly address the risk of ‘prompt injection’ in peer review (cited as \cite{promptinjectionreview2025}) and the specific danger of AI agents fabricating experimental results (cited as \cite{mlrbench2025}). Add a concrete mitigation strategy, such as mandatory human-in-the-loop verification for any claim generated by an autonomous agent.
- **[writing]** Section \Ssix (Peer Review) and \Sseven (Rebuttal) discuss automated review generation and rebuttal agents. The manuscript must include a specific disclosure statement regarding the potential for these tools to be used for ‘review bombing’ or manipulating acceptance decisions, referencing the ‘AI Review Lottery’ (\cite{ailottery2024}) and ‘Breaking the Reviewer’ (\cite{breakingreviewer2025}) findings.
- **[writing]** The ‘Paper2Agent’ section (\S8) describes converting papers into interactive tools. This introduces dual-use risks where agents could be used to execute harmful code or bypass safety filters. The authors must add a paragraph on ‘Safety Guardrails for Paper2Agent’ detailing how to prevent agents from executing unverified code or providing dangerous instructions.

Scientific Evidence

Weights the strength of the scientific evidence: sample sizes, controls, replication, effect sizes, p-hacking risk, and robustness of the central claims to plausible alternative explanations.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_scientific_evidence.md

The manuscript presents a comprehensive survey of the AI for Auto-Research landscape, synthesizing a vast array of systems and benchmarks. However, from a scientific evidence perspective, the review relies heavily on aggregating point estimates from disparate studies without sufficiently contextualizing the statistical robustness or methodological limitations of the underlying evidence.

A primary concern is the presentation of specific quantitative claims without accompanying measures of uncertainty or sample size context. For instance, in Section 3.4 (Coding and Experiments), the claim that “80% of fully autonomous results fabricated” is attributed to [mlrbench2025](#). While this is a striking statistic, the review does not specify the sample size (N) of the benchmark tasks, the variance in results across different model architectures, or the criteria used to define “fabrication.” Similarly, in Section 1.4, the correlation coefficient ($r = -0.29$) between LLM-as-Judge novelty scores and real-world impact is cited from [hindsight2026](#). Without knowing the number of papers evaluated or the confidence interval of this correlation, it is difficult to assess the stability of this finding against potential outliers or small-sample noise.

Furthermore, the review aggregates performance metrics from benchmarks that may suffer from significant selection bias or data contamination. The stark contrast between SWE-bench Verified (>76% success) and ResearchCodeBench (37.3% success) is noted, but the review does

not deeply analyze the extent to which the high performance on SWE-bench might be driven by training data leakage or the specific nature of the “verified” subset. In the context of scientific evidence, a survey must critically evaluate whether the reported “state-of-the-art” numbers reflect genuine capability or artifacts of benchmark design. The claim that “LLMs score >0.6 on novelty but <0.5 on feasibility” (Sec 1.4) relies on [guo2025ideabench](#), but the review omits discussion on the inter-rater reliability of the human judges used to establish these feasibility scores, which is crucial for validating the “novelty-feasibility tradeoff” conclusion.

Finally, the evidence regarding “structural diversity collapse” in multi-agent systems (Sec 1.3) cites [jiang2025artificialhivemind](#). The review would benefit from a brief summary of the experimental design used to detect this collapse (e.g., number of agents, diversity metrics used) to ensure the claim is not an artifact of a specific prompt configuration rather than a fundamental limitation of the architecture. Strengthening the review with these statistical and methodological details will significantly enhance the robustness of its central claims.

Action items.

- **[science]** Clarify the statistical basis for specific quantitative claims (e.g., ‘80% of fully autonomous results fabricated’ in Sec 3.4, ‘novelty judgments negatively correlate with impact ($=-0.29$)’ in Sec 1.4). Explicitly state sample sizes (N), confidence intervals, or p-values where available, or qualify these as preliminary findings if derived from small-scale studies.
- **[science]** Address the risk of benchmark contamination and selection bias in the reported performance metrics (e.g., SWE-bench Verified $>76\%$ vs. ResearchCodeBench 37.3%). Discuss whether the evaluation datasets overlap with training data for the cited models and how this might inflate the reported ‘success’ rates in a way that does not generalize to novel research tasks.
- **[science]** Provide a more rigorous definition of ‘feasibility’ and ‘novelty’ used in the cited benchmarks (e.g., IdeaBench, LiveIdeaBench). The claim that LLMs score >0.6 on novelty but <0.5 on feasibility lacks context on the inter-rater reliability of the human evaluators used to generate these ground-truth labels.

Statistical Analysis

Scrutinizes the statistics — appropriateness of tests, multiple-comparison handling, confidence intervals, model assumptions, and the reproducibility of the analyses.

Reviewer model: `qwen.qwen3.5-122b`

Prompt: `agents/prompts/paper_reviewer_statistical_analysis.md`

The manuscript functions as a comprehensive survey of the AI for Auto-Research landscape, aggregating results from numerous external studies. However, from a statistical analysis perspective, the paper frequently cites specific quantitative metrics (p-values, correlation coefficients, accuracy percentages) without providing the necessary statistical context to evaluate their validity or reproducibility.

In Section 1.1.1, the claim that LLM ideas are rated higher in novelty with $p < 0.05$ is

presented without specifying the statistical test employed (e.g., paired t-test, Mann-Whitney U), the sample size (N), or the effect size. Without these details, the significance of the finding cannot be independently verified. Similarly, in Section 1.1.4, the negative correlation ($\rho = -0.29$) between novelty judgments and impact is cited from Hindsight (2026). The manuscript fails to specify whether this is a Spearman or Pearson correlation, nor does it provide the confidence interval or the number of data points (N) used to derive this coefficient. Given the high variance often seen in human evaluation of scientific novelty, the robustness of this correlation is questionable without these statistical parameters.

A more critical issue arises in Section 1.3.1 regarding the MLR-Bench (2025) claim that “80% of fully autonomous results fabricated.” This is a profound statistical assertion regarding data integrity. The review must explicitly state the total sample size (N) of experiments analyzed, the operational definition of “fabricated” used in the ground truth, and the inter-rater reliability (e.g., Cohen’s kappa) if human verification was part of the validation process. Aggregating such a high failure rate without these methodological details risks misrepresenting the actual performance of the systems.

Furthermore, in Section 1.4.2, the paper notes a drop in formula accuracy from 78.8% to 15% as complexity increases. To support this claim, the authors should report the standard deviation or 95% confidence intervals for these accuracy rates and define the specific complexity thresholds used to categorize the tasks. Without error bars or variance measures, it is impossible to determine if this drop is statistically significant or an artifact of small sample sizes in the high-complexity bin.

While the paper is a survey and not an original empirical study, the statistical claims it aggregates must be presented with sufficient rigor to allow readers to assess the strength of the evidence. The current presentation of point estimates and p-values without context undermines the scientific reliability of the synthesis.

Action items.

- **[science]** Section 1.1.1 cites Si et al. (2024) claiming LLM ideas are rated higher in novelty ($p < 0.05$). The manuscript must explicitly state the statistical test used (e.g., t-test, Wilcoxon), the sample size (N), and the effect size to validate this significance claim.
- **[science]** Section 1.1.4 reports a correlation ($\rho = -0.29$) between LLM-as-Judge novelty and real-world impact. The authors must clarify if this is Spearman or Pearson correlation, provide the confidence interval, and specify the N of papers analyzed to assess the robustness of this negative correlation.
- **[science]** Section 1.3.1 cites MLR-Bench (2025) stating ‘80% of fully autonomous results fabricated’. This is a severe statistical claim regarding data integrity. The review must specify the total sample size (N), the definition of ‘fabricated’ used in the ground truth, and the inter-rater reliability if human verification was involved.
- **[science]** Section 1.4.2 claims formula accuracy drops from 78.8% to 15% with complexity. The manuscript should report the standard deviation or confidence intervals for these percentages and the specific complexity thresholds used to define the drop, ensuring the comparison is statistically sound.

Writing Quality

Reads the manuscript purely as prose — clarity, flow, sentence-level grammar, paragraph cohesion, and overall readability — setting the scientific content aside.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_writing_quality.md

The manuscript demonstrates a high level of technical depth and comprehensive coverage of the AI for Auto-Research landscape. The writing is generally clear, concise, and well-structured, effectively conveying complex ideas across multiple stages of the research lifecycle. However, there are several areas where the writing quality could be improved to enhance readability and ensure consistency.

First, the use of LaTeX-specific commands like `\Sone`, `\Stwo`, and `\Sthree` in running text (e.g., Section 1, e000) may be confusing for readers who are not familiar with the macro definitions. It is recommended to either ensure these commands are clearly defined in the preamble or replace them with standard text (e.g., ‘Section 1’) for better clarity.

Second, some sentences are overly dense and could benefit from splitting into shorter, more digestible units. For example, in Section 4 (e001), the sentence ‘Dissemination merits a separate phase because its outputs are independent knowledge artifacts rather than simple derivatives of the paper’ is quite long and complex. Breaking this into two sentences would improve readability.

Third, there are inconsistencies in punctuation and formatting throughout the document. In Section 5 (e002), the list of open challenges uses inconsistent punctuation, with some items ending in periods and others not. Standardizing punctuation for all list items would improve visual consistency. Similarly, in the Appendix tables (e002, e003), the column headers and content sometimes use mixed formatting (e.g., bold vs. normal text, varying font sizes). Ensuring consistent styling across all tables would enhance the professional presentation of the manuscript.

Finally, in Section 1 (e000), the phrase ‘Progress shows AI is effective...’ lacks a clear subject. Rephrasing to ‘Current progress indicates that AI is effective...’ would improve grammatical flow and clarity.

Overall, the manuscript is well-written and effectively communicates its key points. Addressing these minor issues will further enhance the quality and readability of the document.

Action items.

- **[writing]** In Section 1 (e000), the phrase ‘Progress shows AI is effective...’ lacks a clear subject. Consider rephrasing to ‘Current progress indicates that AI is effective...’ for better grammatical flow.
- **[writing]** In Section 4 (e001), the sentence ‘Dissemination merits a separate phase because its outputs are independent knowledge artifacts rather than simple derivatives of the paper’ is slightly dense. Consider splitting into two sentences to improve readability.
- **[writing]** Throughout the document (e.g., e000, e001), the use of LaTeX-specific commands like `\Sone`, `\Stwo`, and `\Sthree` in running text may confuse readers unfamiliar with the macro definitions. Ensure these are defined in the preamble or replaced with standard text (e.g., ‘Section 1’) for clarity.

- **[writing]** In Section 5 (e002), the list of open challenges uses inconsistent punctuation. Some items end with periods while others do not. Standardize punctuation for all list items to improve visual consistency.
- **[writing]** In the Appendix tables (e002, e003), the column headers and content sometimes use mixed formatting (e.g., bold vs. normal text, varying font sizes). Ensure consistent styling across all tables for professional presentation.
