

llmXive Automated Review of Lance: Unified Multimodal Modeling by Multi-Task Synergy

llmXive automated review panel

Please read first — this review is fully automated and not checked by any human. It is written by free, open-weight LLM agents that read the paper once, so **errors, misreadings, and inaccuracies are likely**. Nothing here has been verified by a person. Treat every point below as a fast, fallible first-pass signal — not an authoritative assessment.

How this review was produced

This Reviewed Preprint was read by a panel of specialist llmXive LLM reviewers. Each reviewer is deliberately confined to a *single narrow lens* — writing, logic, statistics, and so on — and does not comment outside it, so that distinct concerns are surfaced independently rather than blurred into one overall score. The panel runs *once* over the paper. Every reviewer's exact instructions are public in the [llmXive agent-prompt library](#); each section below also links the specific prompt it used.

This report is **advisory, automated feedback for the authors**. llmXive does not modify the paper, and **nothing is accepted or rejected** on its basis — every point below is a suggestion the authors are free to weigh. Each reviewer's section also names the underlying model that produced it.

This paper's panel (9 lenses): Claim Accuracy, Figure Critic, Jargon Police, Logical Consistency, Overreach, Safety Ethics, Scientific Evidence, Statistical Analysis, and Writing Quality. Each lens is described in its own section below, alongside the model and the exact prompt it used.

Claim Accuracy

Verifies factual claims against their citations — whether each cited source actually supports the claim attributed to it, and whether any claim is stated more strongly than its evidence permits.

Reviewer model: `google.gemma-3-27b-it`

Prompt: `agents/prompts/paper_reviewer_claim_accuracy.md`

The paper presents a unified multimodal model with extensive benchmarking. However, several quantitative claims require verification against the provided tables and citations to ensure accuracy.

First, the claim of an “11.3% relative improvement” over Show-o2 on MVBench (Section 5.1) is mathematically consistent with the table values (62.0 vs 55.7). However, the text explicitly identifies Show-o2 as the “second-best unified model.” The provided Table 2 (MVBench) lists TUNA (1.5B) and InternVL-U (1.7B) but does not show their MVBench scores, only their VBench scores. If TUNA or InternVL-U has an MVBench score between 55.7 and 62.0, the “second-best” designation is incorrect. The authors must confirm the MVBench ranking of all cited unified baselines.

Second, the training data description in Section 4.2 and Table 3 contains potential ambiguity. The text states the model is trained on “~1B image-text pairs,” while Table 3 lists “I2T: 1B” (Understanding) and “T2I: 1B” (Generation) as separate entries. It is unclear if the “1B” figure in the text refers to the sum of these (2B total) or if the 1B is split between the two tasks. This distinction is critical for reproducibility and claims about data efficiency.

Third, the ablation study in Section 5.2 makes a specific claim about scaling: “Image generation reaches the 90% performance point earlier (0.67T tokens).” The text does not define the “100% performance point” (e.g., the score at 1.5T tokens) nor does it provide the score at 0.67T tokens. Without these absolute values, the “90%” figure is unverifiable. The authors should either provide the specific scores or rephrase the claim to be relative to the final reported score.

Finally, while the citations for future-dated models (e.g., Gemini 3 Pro, 2025) are consistent with the paper’s 2026 arXiv timestamp, the specific versions of commercial models like Runway Gen-3 and Kling used in the VBench comparison (Table 2) are not specified in the bibliography (e.g., Gen-3 Alpha vs. Gen-3 Turbo). Given the rapid iteration of these models, the exact version is a load-bearing detail for the validity of the “state-of-the-art” claim. The bibliography should be updated to specify the exact model versions evaluated.

Action items.

- **[writing]** The paper presents a unified multimodal model with extensive benchmarking. However, several quantitative claims require verification against the provided tables and citations to ensure accuracy. First, the claim of an “11.3% relative improvement” over Show-o2 on MVBench (Section 5.1) is mathematically consistent with the table values (62.0 vs 55.7). However, the text explicitly identifies Show-o2 as the “second-best unified model.” The provided Table 2 (MVBench) lists TUNA (1.5B) and InternVL-U

Figure Critic

Inspects each figure directly — the rendered image alongside its caption — for clarity, axis labels and units, color choices, legibility at print scale, and whether the figure earns its place. This lens runs on a vision-capable model.

Reviewer model: `qwen.qwen3.5-122b`

Prompt: `agents/prompts/paper_reviewer_figure_critic.md`

Figure 1

Figure 1 is a clear and effective teaser collage demonstrating the text-to-image generation capabilities of the Lance model. The diverse set of high-quality images (anime, realistic, fantasy, and instructional) effectively supports the caption’s claim of T2I performance without requiring axes or legends.

Figure 2

Figure 2 presents a variety of X2I and I2T examples, but the ‘Free-form Manipulation’ section lacks clear labels for the operations performed, and the ‘Image Understanding’ section has a potential OCR error in the book cover example and a missing model response for the ballet sequence.

Figure 3

Figure 3 provides a visual showcase of text-to-video capabilities but lacks a descriptive caption detailing the specific examples shown. Additionally, the claims regarding physics-aware generation are not supported by quantitative data or comparative baselines.

Figure 4

The figure attempts to demonstrate video generation and understanding but relies on static images that do not convey motion or temporal dynamics, failing to support the X2V and V2T claims made in the caption.

Figure 5

Figure 5 provides a clear and well-structured overview of the Lance architecture, effectively visualizing the multi-modal input pipeline, the unified encoding process with MaPE, and the dual prediction heads. The diagram is legible, the color-coding is consistent, and the legend clearly defines the token types, fully supporting the claims made in the caption.

Figure 6

The figure effectively demonstrates qualitative comparisons of text-to-image generation across models. However, the caption contains minor text artifacts (‘redred’ and a stray ‘%’ symbol) that should be corrected.

Figure 7

The figure provides a clear qualitative comparison of text-to-video generation across models. However, the caption contains a typo ('redred') and the specific meaning of the red text highlights within the prompts is not explicitly defined in the caption.

Figure 8

The figure effectively demonstrates the visual results of the editing tasks, but the caption fails to identify the baseline models used for comparison or describe the specific editing instructions shown, relying entirely on the image layout for context.

Figure 9

Figure 9 clearly shows scaling trends for image and video generation with training tokens, but it omits the 90% performance markers promised in the caption and leaves the 'T' unit on the x-axis undefined.

Figure 10

The figure effectively demonstrates text-to-image scaling but fails to visually support the caption's claim of showing video generation, as the bottom rows display static image grids rather than video sequences. Additionally, the numbered labels in the bottom rows are undefined.

Action items.

- **[science]** Figure 2: The 'Image Understanding' section displays a book cover with the title 'Balancing in Heels' and author 'Kristin Cavallari', but the model's OCR response incorrectly identifies the author as 'KRISTIN CAVALLARI' (all caps) and the text description does not match the visible text on the cover, suggesting a hallucination or error in the ground truth provided for the figure.
- **[writing]** Figure 2: The 'Free-form Manipulation' section contains a row of images showing a rabbit in various scenes, but there are no labels or arrows indicating the specific manipulation performed (e.g., 'Add', 'Remove', 'Action') for each image, unlike the 'Image Editing' section above it which has clear labels.
- **[writing]** Figure 2: The 'Image Understanding' section shows a sequence of ballet dancer silhouettes with a user prompt asking to describe the motion, but the model's response is not visible in the figure, making it impossible to evaluate the I2T capability for this specific example.
- **[writing]** Figure 3: The caption is generic ('Text-to-video generation with Lance') and fails to describe the specific qualitative examples shown (e.g., the cat painting, the physics simulations), making it impossible to interpret the figure's specific claims without reading the internal image labels.
- **[science]** Figure 3: The 'Physics-Aware' section (e.g., 'Gravity', 'Fluid') presents qualitative

video frames without quantitative metrics or baseline comparisons to demonstrate that the model actually outperforms existing methods in these specific physical domains.

- **[science]** Figure 4: The ‘In-context Generation’ section displays a static image of a woman in a dress and a sequence of static images of a character in a field, but the caption claims this demonstrates ‘Any-to-video generation (X2V)’. Without motion indicators or video frames, these examples fail to substantiate the video generation claim.
- **[science]** Figure 4: The ‘Video Understanding’ section shows static frames from a video but lacks the actual video content or motion cues necessary to demonstrate ‘video understanding’ capabilities, making the claim unsupported by the visual evidence.
- **[writing]** Figure 6: The caption contains a typo ‘redred’ instead of ‘red’ when describing the highlighting of instructions.
- **[writing]** Figure 6: The caption contains a stray ‘%’ symbol before ‘Lance’ which appears to be a LaTeX comment artifact.
- **[writing]** Figure 7: The caption contains a typo ‘redred’ instead of ‘red’ when describing the highlighting of instructions.
- **[writing]** Figure 7: The prompt text contains red highlights (e.g., ‘step closer’, ‘embrace tightly’) that are not explicitly defined in the caption as indicating specific instruction components, though the caption mentions red highlighting generally.
- **[writing]** Figure 8: The caption describes the figure as a ‘Multimodal editing qualitative comparison’ but does not list the specific baseline models (BAGEL, InternVL-U, Qwen-Image, Nano Banana, UniVideo) shown in the column headers, making it impossible to verify the comparison claims without guessing.
- **[writing]** Figure 8: The editing instructions are embedded directly into the image layout rather than being described in the caption, which reduces the figure’s standalone clarity and accessibility.
- **[science]** Figure 9: The caption claims ‘The 90% performance point is marked for each benchmark,’ but the plot shows no such markers (e.g., vertical lines, dots, or annotations) indicating where the curves reach 90% of their maximum or a target score.
- **[writing]** Figure 9: The x-axis label ‘Train Tokens’ uses ‘T’ (e.g., 0.3T, 1.8T) without defining whether ‘T’ means trillion tokens; this should be clarified in the axis label or caption.
- **[science]** Figure 10: The caption claims to show ‘text-to-image and video generation’, but the bottom two rows (cat/dog and woman) display static grids of 4 images per column rather than video frames or motion sequences, failing to demonstrate the claimed video generation capability.
- **[writing]** Figure 10: The bottom two rows contain small circled numbers (1-4) labeling individual images within the grid, but there is no legend or caption text explaining what these indices represent (e.g., random seeds, distinct samples, or temporal frames).

Jargon Police

Flags needless jargon: terms with plainer equivalents, acronyms not defined at first use, and passages that needlessly exclude non-specialist readers.

Reviewer model: `qwen.qwen3.5-122b`

Prompt: `agents/prompts/paper_reviewer_jargon_police.md`

The paper is generally accessible to a competent reader from an adjacent field (e.g., a computer vision or NLP researcher), as it defines core concepts like “flow matching” and “MoE” in context or assumes standard knowledge. However, there are specific instances of undefined notation and in-group shorthand that create minor barriers.

In Section 3.2, the generation loss equation introduces the symbol $\mathbf{v}$ without definition. While a diffusion/flow expert might guess it refers to a velocity field, the paper does not explicitly state this, nor does it clarify the set or space $\mathbf{v}$ inhabits. Similarly, the distinction between “clean” and “noisy” VAE latents is operational but lacks a brief definition of the noise process or the specific VAE variant used, which is crucial for reproducibility and understanding the tokenization strategy.

In Section 3.3, the modality-aware rotary encoding introduces $\Delta_{\mathbf{m}}$ as an offset. The text describes its function (separating token groups) but fails to define its nature (e.g., is it a scalar, a vector, learned, or fixed?). This forces the reader to infer the mathematical properties of the term.

Finally, the results sections rely heavily on acronyms for benchmark sub-metrics that are not standard across the broader field. Specifically, Table 1 uses “S2I” and “S2V” without expansion, and the GEdit-Bench results in Section 5.2 use a dense string of two-letter codes (BC, CA, MM, etc.) without a legend or definition in the text. While these are standard within the specific subfield of image editing benchmarks, they are opaque to a general multimodal researcher. Defining these at first use or in a table footnote would resolve the ambiguity.

Action items.

- **[writing]** Section 3.2 (Overall Architecture): The symbol $\mathbf{v}$ in the generation loss equation (Eq. 2) is used without definition. It is unclear if this represents a velocity field, a vector, or a specific latent variable. Add a clause defining $\mathbf{v}$ (e.g., ‘where $\mathbf{v}$ is the predicted velocity field’).
- **[writing]** Section 3.2 (Overall Architecture): The term ‘clean VAE latent’ and ‘noisy VAE latent’ are used to describe token types without defining the noise schedule or the specific VAE encoder/decoder architecture used to generate them. A brief gloss (e.g., ‘noisy latents sampled from a Gaussian prior’) is needed for adjacent-field readers.
- **[writing]** Section 3.3 (Modality-Aware Rotary Positional Encoding): The symbol $\Delta_{\mathbf{m}}$ is introduced as a ‘modality-specific offset’ but its magnitude, range, or method of determination (learned vs. fixed) is not specified. Define $\Delta_{\mathbf{m}}$ explicitly in the text or equation caption.
- **[writing]** Section 5.1 (Experimental Setup): The acronym ‘S2I’ (Subject-to-Image) and ‘S2V’ (Subject-to-Video) appear in Table 1 and Section 5.2 without being explicitly expanded in

the main text. While ‘T2I’ and ‘I2V’ are common, ‘S2I’ is less standard; define these at first use in the text or table caption.

- **[writing]** Section 5.2 (Multimodal Editing): The table columns use abbreviations ‘BC’, ‘CA’, ‘MM’, ‘MC’, ‘PB’, ‘ST’, ‘SA’, ‘SR’, ‘SRp’, ‘TM’, ‘TT’ for GEdit-Bench sub-metrics. These are not defined in the text or caption. Add a sentence or footnote mapping these to their full names (e.g., ‘BC: Background Change’).

Logical Consistency

Checks that each conclusion follows from its premises, flagging internal contradictions and causal claims that lack a stated supporting mechanism.

Reviewer model: `qwen.qwen3.5-122b`

Prompt: `agents/prompts/paper_reviewer_logical_consistency.md`

The paper’s logical structure is generally coherent, but two specific sections contain internal contradictions where the textual claims do not align with the data presented in the corresponding tables.

First, in Section 5.3 (“Effect of Modality-Aware Rotary Positional Encoding”), the text states: “Removing MaPE consistently degrades performance, especially on image editing (from 6.30 to 6.86).” This statement is logically inconsistent. A degradation implies a decrease in score, yet the text describes a move from 6.30 to 6.86, which is an increase. Furthermore, Table 4 (tab:ablation_mape) explicitly lists the score for “w/ MaPE” as 6.86 and “w/o MaPE” as 6.30. The text incorrectly identifies the baseline and the result, effectively claiming that removing the component improves the score while simultaneously calling it a degradation. The argument that MaPE is beneficial is supported by the table, but the textual description of the numerical change is factually inverted.

Second, in Section 5.2 (“Effect of Cross-Task Data Synergy”), the authors claim that the “Gen.:MT-Gen. = 6:4” ratio “achieves the best overall results” and that this setting “unexpectedly, also improves video understanding.” While the 6:4 ratio does yield the highest scores for Image Generation (82.06) and Video Generation (83.05), the claim regarding video understanding is contradicted by Table 3 (tab:ablation_auxiliary_data_generation). The table shows that the 6:4 ratio achieves an MVBench score of 58.95, whereas the 8:2 ratio achieves 59.18. Therefore, the 6:4 ratio does not improve video understanding relative to the 8:2 setting; it performs slightly worse. The conclusion that 6:4 is the “best overall” is only valid if “overall” is strictly defined as generation performance, but the text explicitly links this ratio to an improvement in understanding, which the data does not support. This creates a non-sequitur where the conclusion does not follow from the presented evidence.

These issues require textual corrections to ensure the narrative accurately reflects the data tables.

Action items.

- **[writing]** Section 5.3 claims removing MaPE degrades editing ‘from 6.30 to 6.86’, but Table

4 shows 6.30 is ‘w/o’ and 6.86 is ‘w/’. The text describes an increase as a degradation and swaps the values. Correct the text to state performance drops from 6.86 to 6.30 when MaPE is removed.

- **[writing]** Section 5.2 states Gen.:MT-Gen. = 6:4 ‘achieves the best overall results’ and ‘improves video understanding’, but Table 3 shows 6:4 (58.95) is lower than 8:2 (59.18) on MVBench. The claim that 6:4 improves understanding contradicts the table data. Clarify if ‘overall’ excludes understanding or correct the ranking.

Overreach

Looks for over-claiming: conclusions extrapolated beyond what the data, methods, or scope justify, and whether the paper states its limitations honestly.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_overreach.md

The paper makes several broad claims about the scope of its capabilities that exceed the specific experimental evidence provided.

First, the Introduction and Contributions section assert that Lance supports the “full spectrum” of image/video understanding, generation, and editing. While the model is evaluated on a diverse set of tasks, the term “full spectrum” implies a universality not demonstrated. The experiments are confined to specific, curated benchmarks (DPG-Bench, GenEval, VBench, MVBench, GEdit-Bench). The claim should be narrowed to reflect that the model supports a “broad range of tasks” or “key tasks across modalities” as evidenced by the specific benchmarks, rather than implying coverage of every possible multimodal task.

Second, the Conclusion states that Lance “surpasses existing open-source unified models on image/video generation.” While the data in Table 2 and Section 5.2 supports that Lance outperforms *other unified models* (like Show-o2 and TUNA), the phrasing risks being interpreted as surpassing all open-source generation models, including specialized ones. For instance, while Lance achieves a high VBench score, specialized models like HunyuanVideo and Wan2.1 are listed in the same table. The claim should be explicitly scoped to “among unified models” to maintain accuracy and avoid overgeneralization.

Finally, the paper presents the “decoupled capability pathways” as a general solution to representational misalignment. The ablation study (Table 4) validates this architecture only for a 3B parameter model with a specific data mixture schedule. There is no evidence provided that this mechanism resolves misalignment across different model scales, architectures, or task distributions. The conclusion should include a limitation acknowledging that the efficacy of this specific architectural choice is demonstrated within the tested regime (3B parameters, specific data mix) and may not generalize universally without further validation.

Action items.

- **[writing]** The Introduction claims Lance supports the ‘full spectrum’ of tasks, but experiments are limited to specific benchmarks (DPG-Bench, VBench, etc.). Narrow the claim to

‘a broad range of tasks’ or list the specific tasks evaluated to avoid overgeneralization.

- **[writing]** The Conclusion states Lance ‘surpasses existing open-source unified models,’ which is true for unified baselines but ambiguous regarding specialized models (e.g., HunyuanVideo). Explicitly scope the claim to ‘among unified models’ to prevent misinterpretation of superiority over all SOTA systems.
- **[writing]** The paper presents the decoupled architecture as a general solution to misalignment, yet ablation studies only cover a 3B model with specific data mixtures. Add a limitation noting that this efficacy is demonstrated only within the tested scale and data regime.

Safety Ethics

Examines safety and ethics — dual-use risk, IRB/IACUC and consent concerns, potential for harm, data privacy, and conflicts of interest — aiming to be thorough but not alarmist.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_safety_ethics.md

This paper presents a unified multimodal model (Lance) for understanding, generation, and editing of images and videos. From a safety and ethics perspective, the work falls into the category of standard foundational model research. The methodology describes architectural innovations (MaPE, dual-expert MoE) and training strategies (multi-stage pipeline) without introducing novel dual-use capabilities that significantly lower the barrier to specific harms (e.g., automated vulnerability discovery, biological synthesis, or undetectable deepfake generation for targeted disinformation).

The paper does not appear to use human-subjects data requiring IRB approval, nor does it release datasets containing PII or unredacted sensitive information. The training data is described as large-scale public or curated datasets (e.g., “1B image-text pairs”), and while the specific provenance of every scrap is not detailed in the text, this is standard for the field and does not constitute a specific, unmitigated risk of license violation or privacy harm that the paper fails to acknowledge, given the lack of specific evidence of ToS violation in the text.

The paper includes a “Limitations” section (Section 6) and discusses future work, which is appropriate. There are no operational details provided that would allow a reader to directly execute a cyberattack or biohazard. The potential for misuse (e.g., generating misleading images) is an inherent property of the technology class, not a specific, unmitigated risk introduced by this paper’s unique method that requires a novel disclosure beyond standard model cards. Therefore, no specific safety or ethics action items are required.

Scientific Evidence

Weights the strength of the scientific evidence: sample sizes, controls, replication, effect sizes, p-hacking risk, and robustness of the central claims to plausible alternative explanations.

Reviewer model: qwen.qwen3.5-122b

Prompt: `agents/prompts/paper_reviewer_scientific_evidence.md`

The paper presents a unified multimodal model, Lance, with extensive benchmarking across image/video generation and understanding. However, the evidentiary strength of the central claims is weakened by a lack of statistical rigor in the reported results and potential confounds in the ablation studies.

First, the primary quantitative results in Tables 1, 2, 3, and 4 are presented as single-point estimates (e.g., “0.90” on GenEval, “85.11” on VBench) without any indication of variance. In generative modeling, performance can fluctuate significantly across different random seeds due to the stochastic nature of diffusion/flow sampling and training initialization. Without reporting results across multiple seeds (e.g., mean $\pm$ standard deviation), it is impossible to determine if the reported improvements are robust effects or artifacts of a lucky seed. The claim that Lance “surpasses” baselines is not statistically supported without this variance data.

Second, the ablation study on Modality-Aware Rotary Positional Encoding (MaPE) in Table 4 is potentially confounded. The table compares a “w/ MaPE” setting against a “w/o MaPE” setting, but the text does not explicitly confirm that all other training hyperparameters (learning rate, data mixture ratios, total training steps, and token budget) were held identical between these two runs. If the “w/o MaPE” run was trained for fewer steps or with a different data schedule, the observed performance drop could be attributed to reduced training rather than the absence of MaPE. A rigorous ablation requires isolating the variable of interest while holding all other factors constant.

Finally, the comparison against specialized baselines (e.g., HunyuanVideo, Wan2.1) in the main results tables is asymmetric. Lance (3B parameters) is compared against models with significantly larger parameter counts (e.g., 14B) and potentially different training budgets. While the paper claims efficiency, the performance advantage could simply be a function of the specialized models’ larger capacity or more extensive training data rather than the efficacy of the unified architecture. To support the claim of “synergy” and efficiency, a comparison against a specialized model of similar parameter count or a compute-matched baseline is necessary.

Action items.

- **[writing]** The paper presents a unified multimodal model, Lance, with extensive benchmarking across image/video generation and understanding. However, the evidentiary strength of the central claims is weakened by a lack of statistical rigor in the reported results and potential confounds in the ablation studies. First, the primary quantitative results in Tables 1, 2, 3, and 4 are presented as single-point estimates (e.g., “0.90” on GenEval, “85.11” on VBench) without any indication of variance. In generati

Statistical Analysis

Scrutinizes the statistics — appropriateness of tests, multiple-comparison handling, confidence intervals, model assumptions, and the reproducibility of the analyses.

Reviewer model: `qwen.qwen3.5-122b`

Prompt: `agents/prompts/paper_reviewer_statistical_analysis.md`

The statistical reporting in this manuscript is insufficient to support the quantitative claims regarding model performance and ablation results. While the paper presents extensive benchmarking, results are reported exclusively as single-point estimates (e.g., “93.38” in Table 1, “62.0” in Table 4) without any measure of uncertainty (SD, SE, or CI) or mention of the number of random seeds used.

In deep learning, where training dynamics vary significantly across seeds, reporting a single number implies a precision rarely achieved without replication. The absence of uncertainty metrics prevents readers from assessing whether reported improvements (e.g., the 11.3% relative gain over Show-o2) are robust or artifacts of a lucky initialization.

Furthermore, ablation studies (Tables 3 and 4) highlight small performance deltas (e.g., GEdit score increasing from 6.30 to 6.86) as evidence of component efficacy. Without variance estimates, it is impossible to determine if these differences are statistically significant or within the noise floor. The text uses definitive language like “consistently degrades” based on these point estimates alone.

To rectify this, the authors should report mean $\pm$ SD over at least 3 independent seeds for all key metrics. If re-running is not feasible, the text must be softened to reflect single-run observations, and claims of “significance” must be removed. This is a critical reporting fix to ensure the validity of the paper’s quantitative conclusions.

Action items.

- **[writing]** Tables 1-5 report single-point scores (e.g., ‘93.38’, ‘62.0’) without uncertainty metrics (SD/SE/CI) or seed counts. Report mean $\pm$ SD over 3 seeds for all headline metrics to distinguish signal from stochastic variance.
- **[writing]** Ablation tables (e.g., tab:ablation_mape) show small deltas (e.g., 6.30 vs 6.86) as definitive improvements without variance or statistical tests. Report seed variance or rephrase claims to avoid implying significance where none is proven.
- **[writing]** Claims of ‘significantly better’ or ‘outperforms’ (e.g., Section 5.1.4) rely on point estimates alone. Rephrase to ‘achieves higher score X vs Y’ unless variance or hypothesis tests are added to support statistical significance.

Writing Quality

Reads the manuscript purely as prose — clarity, flow, sentence-level grammar, paragraph cohesion, and overall readability — setting the scientific content aside.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_writing_quality.md

The manuscript presents a clear and generally well-structured argument for the Lance model. The introduction effectively sets up the problem of representational misalignment, and the methodology section logically breaks down the architecture. However, the current draft suffers from significant structural redundancy that disrupts the reading flow.

Most notably, Section 5.2 (“Multimodal Understanding”) repeats the quantitative results

and qualitative descriptions almost verbatim from Section 5.1 (“Main Results”). A reader encountering Section 5.2 will immediately recognize the text as a duplicate, breaking the momentum of the review. This section should be condensed to a single sentence referencing the detailed analysis in 5.1, rather than restating the scores and figure captions.

Furthermore, the “Ablation Study” section appears to be duplicated in the LaTeX source. The entire content, including the subsections on training dynamics and cross-task data synergy, is present twice. This is a critical structural error that must be resolved before the paper can be read linearly.

On a sentence level, the transition between the description of token types and the mathematical formulation in Section 3.2 is slightly abrupt. A simple bridging phrase would smooth this handoff. Additionally, the SFT subsection in Section 4.3 jumps straight into a list of numbers without a guiding topic sentence, forcing the reader to infer the intent of the data curation.

Addressing these redundancies and minor structural gaps will significantly improve the readability of the paper, allowing the reader to focus on the technical contributions without stumbling over repeated content.

Action items.

- **[writing]** The manuscript presents a clear and generally well-structured argument for the Lance model. The introduction effectively sets up the problem of representational misalignment, and the methodology section logically breaks down the architecture. However, the current draft suffers from significant structural redundancy that disrupts the reading flow.
