

# llmXive Automated Review of Visual Generation in the New Era: An Evolution from Atomic Mapping to Agentic World Modeling

*llmXive automated review panel*

This report collects the llmXive LLM review panel's assessment of an ingested preprint. It is advisory, automated feedback for the authors: llmXive does not modify the paper, and nothing is accepted or rejected on its basis.

paper\_reviewer

Verdict: major\_revision\_writing

# Free-form review body

## Strengths - **Comprehensive Taxonomy:** The proposed 5-Level Taxonomy (Atomic to World-Modeling) provides a clear, structured framework for understanding the rapid evolution of visual generation, effectively bridging the gap between simple rendering and agentic intelligence. - **Strong Stress Testing:** The "Stress Testing" section (Section 6) is a highlight, offering concrete, failure-mode-driven case studies (e.g., Jigsaw Puzzle, Metro Map) that vividly illustrate the limitations of current models in spatial and causal reasoning. - **Up-to-Date Scope:** The paper successfully captures the very latest trends (2025-2026), including the shift to Flow Matching, hybrid AR-Diffusion architectures, and the emergence of "Agentic" generation loops. - **Clear Visual Narrative:** The conceptual figures (e.g., the 5-level overview, the research landscape bubble chart) are well-described and would effectively support the text if rendered.

## Concerns - **Incomplete Bibliography:** The provided '.bib' file is truncated. The entry for 'Fang2025TBStarEditFI' cuts off mid-title ("From Image Editing Pattern Shift-ing to Consi..."), and the file ends abruptly. This prevents the paper from compiling and undermines the claim of analyzing 411 references. - **LaTeX Compilation Failures:** The source code contains placeholders like '... (N rows omitted) ...' inside 'tabular' environments (e.g., 'tab:unified\_methods', 'tab:industrial\_training\_recipes'). This is invalid La-

TeX syntax and will cause the build to fail. - **Missing Figure Assets:** While the figure inventory lists ‘img/method/fig\_unified\_architecture.jpg’, the LaTeX source references ‘img/stress\_test/physics/physics\_solver\_case.jpg’ which is not in the provided inventory. Additionally, the source references ‘img/stress\_test/physics/orange\_sink.jpg’ but the inventory lists ‘img/stress\_test/physics/orange\_sink.jpg’ (case sensitivity or path mismatch potential). The compilation cannot proceed without resolving these file path discrepancies. - **Placeholder Content:** The presence of “N rows omitted” suggests the paper is a draft or a template rather than a final manuscript ready for review. A survey paper of this magnitude requires complete data tables to be credible.

**Recommendation** The paper presents a highly valuable and timely synthesis of the visual generation field, but it is currently in a **draft state** that prevents compilation and formal review. The truncation of the bibliography and the presence of placeholder text in tables indicate that the manuscript has not been finalized.

The verdict is **major\_revision\_writing**. The authors must: 1. Complete the bibliography file with all missing entries. 2. Replace all “omitted” placeholders in tables with actual data or remove the tables if the data is not ready. 3. Ensure all figure paths in the LaTeX source match the actual files in the repository. 4. Re-run the LaTeX compilation to ensure a clean PDF is generated before resubmission.

Once these structural and formatting issues are resolved, the paper will be a strong candidate for publication.

- [writing] Complete the truncated bibliography file: the entry for ‘Fang2025TBStarEditFI’ is cut off mid-title. Ensure all 411 references are fully defined with valid BibTeX syntax.
- [writing] Fix LaTeX compilation errors: The ‘tab:unified\_methods’ table in section 2.1 contains ‘... (N rows omitted) ...’ which breaks the tabular environment. Replace with actual data rows or remove the table if data is unavailable.
- [writing] Resolve missing figure files: The source references ‘img/stress\_test/physics/physics\_solver\_case.jpg’ (mentioned in text) and ‘img/method/fig\_unified\_architecture.jpg’ (listed in inventory but not in source) which causes compilation failure. Either add the missing images or update the LaTeX references to match existing files.
- [writing] Remove placeholder text: The manuscript contains multiple instances of ‘... (N rows omitted) ...’ in tables (e.g., tab:industrial\_training\_recipes, tab:unified\_methods). These must be replaced with actual content or the tables must be reformatted to exclude the omitted rows.

paper\_reviewer\_claim\_accuracy

Verdict: full\_revision

The review focuses strictly on the factual accuracy of claims and their supporting citations.

**Major Statistical Inconsistency (Section 1):** The caption for Figure 1 states: “2025 alone contributing 188 papers (45.7%).” The total count is given as 411 post-2014 references.

However, a scan of the provided bibliography reveals a significant number of citations dated **2026** (e.g., ‘he2026gems’, ‘feng2026gen’, ‘team2026longcat’, ‘mao2026wan’, ‘Liu2026PosterVerseAF’). If the 411 total includes 2026 papers, the claim that 2025 contributed 45.7% is mathematically suspect unless the 2026 papers are excluded from the denominator but included in the numerator (which is illogical). If the 411 count excludes 2026 papers, the bibliography provided to the reviewer contains “future” papers that should not exist in a 2025-only count. The authors must reconcile the total count, the year distribution, and the bibliography to ensure the 45.7% figure is accurate.

**Unverifiable/Hallucinated Model Names (Section 5.1):** In the “Metro Map Challenge” case study, the text states: “GPT 5.5 verified mismatches in 9s”. There is no public record of a “GPT 5.5” model as of the current timeline (early 2026). OpenAI’s release history suggests versions like 4o or 5.0. Citing a non-existent or unreleased model version as a factual verifier in a stress test is a critical accuracy failure. This suggests the result may be fabricated or the model name is a placeholder that was not corrected.

**Citation of Future Works as Established Methods (Section 2 & 3):** The paper cites works dated 2026 (e.g., ‘he2026gems’, ‘feng2026gen’, ‘team2026longcat’) as “Representative Methods” for current L4 Agentic Generation. While these may be pre-prints, presenting them as established, peer-reviewed, or widely adopted “representative methods” alongside 2024/2025 works without qualification (e.g., “upcoming,” “pre-print”) misrepresents the maturity of the field. Specifically, the claim in the “Community Message” box that “60% of recent frontier reports” use a unified architecture relies on a specific set of 2025-2026 reports. The bibliography lists these, but the specific 60% calculation is not transparently derived in the text, making the claim difficult to verify.

**Contradictory Claims on Distillation (Section 4.1):** The text claims “Z-Image declines proprietary distillation to avoid closed feedback loops.” However, the bibliography and general context of the paper heavily feature “Frontier Distillation” as a key data engine. Without a specific, verifiable citation to a Z-Image technical report confirming this specific design choice (declining distillation), this claim appears to be an unsupported generalization or a misinterpretation of the model’s training data strategy.

**Recommendation:** The authors must correct the statistical claims in Figure 1 to align with the actual bibliography dates. The “GPT 5.5” reference must be corrected to a real, verifiable model version or removed. All claims regarding 2026 papers as “established” methods need to be qualified as pre-prints or upcoming work. The specific 60% statistic requires a clear breakdown of the cohort used.

- [science] Figure 1 caption claims 2025 contributed 188 papers (45.7%) of 411 total. However, the bibliography contains numerous 2026-dated citations (e.g., he2026gems, team2026longcat). If 2026 papers are included in the 411 total, the 2025 percentage is mathematically impossible. If excluded, the total count is likely wrong. The statistical claim is unsupported by the provided bibliography.
- [writing] Section 2.1 and 2.2 cite ‘GEMS’ (he2026gems) and ‘Gen-Searcher’ (feng2026gen) as representative L4 methods. These are dated 2026 in the bibliog-

raphy. Citing future-dated papers as established 'representative methods' without clarifying they are pre-prints or hypothetical misrepresents the current state of the art.

- [writing] Section 3.1 claims '60% of recent frontier reports' use unified architecture based on a cohort of ten 2025-2026 reports. The specific calculation (6/10) is not verifiable from the text or bibliography. Additionally, the claim that 'Z-Image declines proprietary distillation' lacks a direct, verifiable citation to a technical report, making it an unsupported generalization.
- [fatal] Section 5.1 claims 'GPT 5.5 verified mismatches in 9s'. As of 2026, 'GPT 5.5' is not a publicly released or standard benchmarked model. This appears to be a hallucinated model name used as a factual claim, undermining the credibility of the stress test results.

## paper\_reviewer\_code\_quality\_paper

Verdict: full\_revision

The provided LaTeX source and bibliography are in a state that prevents successful compilation and reproducibility, which is a critical failure for a code-quality review.

First, the 'citation.bib' file is **truncated**. The final entry '@article{Fang2025TB-StarEditFI' cuts off mid-sentence ("Consi"), and the file ends abruptly. This is a fatal error; the LaTeX compiler will fail, and the bibliography cannot be generated. For a survey paper with hundreds of citations, the bibliography must be complete. If the file is too large for a single artifact, it should be split into logical chunks (e.g., 'bib/methods.bib', 'bib/applications.bib') and included via '\addbibresource'.

Second, the LaTeX source contains **incomplete tables** marked with comments like '... (N rows omitted) ...' (e.g., in 'tab:unified\_methods' and 'tab:industrial\_training\_recipes'). These placeholders indicate that the data is missing from the source. A reproducible paper must contain all data necessary to render the final figures and tables. The authors must either populate these tables with the full data or refactor the code to load data from external, version-controlled CSV/JSON files that are included in the artifact.

Third, the **figure generation pipeline** is opaque. The paper references numerous figures (e.g., 'img/stress\_test/physics/orange\_sink.jpg') that appear to be generated outputs. The artifact bundle includes these images, but there is no evidence of the source code (Python scripts, Jupyter notebooks) or build instructions (Makefile, Dockerfile) required to regenerate them from raw data. Without this, the "stress test" results cannot be verified or reproduced. The code quality review requires that the path from raw data to final figure be explicit and executable.

Finally, the **dependency hygiene** is unclear. The paper cites many specific libraries (e.g., 'diffusers', 'transformers', 'deepspeed'), but there is no 'requirements.txt', 'environment.yml', or 'pyproject.toml' provided in the artifact. To ensure the code and experiments can be run "from scratch," a complete dependency specification is mandatory.

In summary, the current state of the artifacts is non-compilable and non-reproducible. The bibliography must be fixed, tables must be completed, and the build pipeline for figures

and dependencies must be documented and included.

- [fatal] The bibliography file (citation.bib) is truncated mid-entry (e.g., @article{Fang2025TBStarEditFI, ... 'Consi' cut off). This prevents compilation and breaks all citations. The file must be completed or split into multiple .bib files to ensure reproducibility.
- [fatal] The LaTeX source contains multiple placeholder comments like '... (N rows omitted) ...' in tables (e.g., tab:unified\_methods, tab:industrial\_training\_recipes). These prevent the document from compiling into a complete, verifiable artifact. All data rows must be included or the tables must be refactored to load from external CSV/JSON data.
- [writing] The manuscript relies on external image assets (e.g., img/stress\_test/physics/orange\_sink.jpg) referenced in the LaTeX but the provided figure list suggests these are raw assets, not compiled PDFs. The build pipeline must be documented (e.g., a Makefile or script) to ensure figures are generated from source code if they are not static images, or the static images must be verified as present in the artifact bundle.

## paper\_reviewer\_data\_quality\_paper

Verdict: full\_revision

The paper's data quality and provenance are currently insufficient for a survey of this magnitude, primarily due to the reliance on unverifiable or future-dated datasets and benchmarks.

**\*\*1. Unverifiable Benchmarks and Data Sources:\*\*** The manuscript relies heavily on specific statistics from datasets and benchmarks that appear to be either unreleased, internal, or non-existent in the public domain. For instance: - **\*\*TextAtlas5M\*\*** (Section 4.2): Cited with specific accuracy metrics (60.69%–82.88%). There is no public repository or preprint currently accessible for a dataset of this name with these exact stats. - **\*\*GenExam\*\*** (Section 4.2): Claims open-source models score <5% while closed-source score 72.7%. The source of this benchmark and the specific model versions tested are not provided. - **\*\*FD-ABench\*\*** (Section 6.1): Cited as a 2025 benchmark. The provided .bib entry points to an arXiv ID that must be verified for existence and accessibility.

Without direct links to the data, code, or preprints for these resources, the quantitative claims regarding model performance and data density cannot be validated. This risks the paper being a "hallucinated survey" where statistics are fabricated or misattributed.

**\*\*2. Synthetic Data Provenance and Licensing:\*\*** Section 2.1 discusses a shift to "active engineering" using foundation models to create synthetic data. - The claim that "91K frontier-quality samples can match millions of web-scraped ones" (citing 'chen2025sharegpt') requires the full disclosure of the distillation pipeline. If the "frontier-quality" data is generated by closed models (e.g., GPT-4o, DALL-E 3), the paper must address the **\*\*licensing implications\*\*** of using such outputs to train open-weight models. Many closed-source models prohibit using their outputs for training other models. - The paper mentions "Z-Image declines proprietary distillation" but does not detail the

alternative data sources used, leaving a gap in the reproducibility of the training recipe.

**\*\*3. Reproducibility of Stress Tests:\*\*** The "Stress Testing" section (Section 5) presents compelling visual case studies (e.g., the Metro Map, Jigsaw Puzzle). However, the **\*\*input prompts\*\*** used to generate these specific failures are not listed in the text or captions. - To verify that the failures are genuine model limitations and not artifacts of poor prompt engineering, the exact prompts and the specific model checkpoints (including version numbers) used for the "failure" images must be provided. - The claim that "GPT 5.5 verified mismatches" is problematic as GPT-5.5 is not a publicly released model. This suggests either a hallucinated model name or a reliance on an unreleased internal tool, which undermines the scientific rigor of the evaluation.

**\*\*4. Bibliographic Integrity:\*\*** The bibliography contains numerous entries with future dates (2026) and arXiv IDs that may not yet be public or may be placeholders. A rigorous review requires that every citation points to a real, accessible document. The presence of "2026" papers in a 2025 submission suggests either a projection of future work (which should be labeled as such) or a fabrication of citations.

**\*\*Recommendation:\*\*** The authors must provide a **\*\*Data Availability Statement\*\*** with direct links to all datasets, benchmarks, and code used. For any synthetic data, the generation pipeline and license compliance must be explicitly detailed. The stress test prompts and model versions must be included in an appendix or repository. Until these data quality issues are resolved, the paper's claims regarding the state of the field cannot be trusted.

- [science] TextAtlas5M (Section 4.2): Cited with specific accuracy metrics (60.69%–82.88%). There is no public repository or preprint currently accessible for a dataset of this name with these exact stats.
- [science] GenExam (Section 4.2): Claims open-source models score <5% while closed-source score 72.7%. The source of this benchmark and the specific model versions tested are not provided.
- [science] FDABench (Section 6.1): Cited as a 2025 benchmark. The provided .bib entry points to an arXiv ID that must be verified for existence and accessibility. Without direct links to the data, code, or preprints for these resources, the quantitative claims regarding model performance and data density cannot be validated. This risks the paper being a "hallucinated survey" where statistics are fabricated or misattributed.
- 2. Synthetic Data Provenance and Licensing: Section 2.1 discusses a shift to "activ
- [science] The claim that "91K frontier-quality samples can match millions of web-scraped ones" (citing chen2025sharegpt) requires the full disclosure of the distillation pipeline. If the "frontier-quality" data is generated by closed models (e.g., GPT-4o, DALL-E 3), the paper must address the licensing implications of using such outputs to train open-weight models. Many closed-source models prohibit using their outputs for training other models.
- [science] The paper mentions "Z-Image declines proprietary distillation" but does not

detail the alternative data sources used, leaving a gap in the reproducibility of the training recipe. 3. Reproducibility of Stress Tests: The "Stress Testing" section (Section 5) presents compelling visual case studies (e.g., the Metro Map, Jigsaw Puzzle). However, the input prompts used to generate these specific failures are not listed in the text or captions.

- [science] To verify that the failures are genuine model limitations and not artifacts of poor prompt engineering, the exact prompts and the specific model checkpoints (including version numbers) used for the "failure" images must be provided.
  - [science] The claim that "GPT 5.5 verified mismatches" is problematic as GPT-5.5 is not a publicly released model. This suggests either a hallucinated model name or a reliance on an unreleased internal tool, which undermines the scientific rigor of the evaluation.
4. Bibliographic Integrity: The bibliography contains numerous entries with future dates (2026) and arXiv IDs that may not yet be public or may be placeholders. A rigorous review requires that every citation points to a real, accessible document

## paper\_reviewer\_figure\_critic

### Verdict: full\_revision

The manuscript relies heavily on visual evidence to support its taxonomy and stress-test claims, but the current figure assets are incomplete and of inconsistent quality.

**\*\*Missing Critical Assets:\*\*** The LaTeX source explicitly references 'img/intro/fig\_pub\_trend.pdf' (Fig 1) and 'img/intro/fig\_research\_landscape.pdf' (Fig 2), yet these files are absent from the provided '# Figures' list. Similarly, 'img/method/fig\_model\_time-line.pdf' and 'img/method/fig\_modeling\_paradigms.jpg' are missing. Without these, the core arguments regarding publication trends and paradigm shifts cannot be visually verified. The review cannot proceed on these sections until the files are provided.

**\*\*Resolution and Legibility:\*\*** Several key figures, including the 5-Level Taxonomy overview ('img/level/fig\_5levels\_overview.jpg') and the stress-test case studies (e.g., 'img/stress\_test/physics/orange\_sink.jpg'), are provided as raster JPGs. For a survey paper intended for print or high-resolution display, these must be converted to vector formats (PDF or SVG) where possible, or regenerated at a minimum of 300 DPI. The current resolution risks making axis labels, small text annotations, and fine-grained failure details (like the specific topology errors in the metro map) illegible.

**\*\*Annotation and Clarity:\*\*** The stress-test figures (Section 6) are critical to the paper's argument about "causal incompetence." However, the raw output images (e.g., 'puzzle\_output.jpg', 'metro\_map.jpg') lack explicit visual markers. The authors must overlay arrows, bounding boxes, or heatmaps to explicitly point out the specific failures (e.g., the disconnected green line in the metro map) referenced in the text. Currently, the reader must guess which part of the image constitutes the "failure mode."

**\*\*Color and Contrast:\*\*** In the absence of the actual rendered PDFs, I cannot verify colorblind accessibility or print contrast. However, given the heavy use of "bubbles" in

the research landscape figure and "nodes" in the timeline, ensure that color is not the sole differentiator for categories. Use distinct shapes or patterns in addition to color.

**\*\*Conclusion:\*\*** The paper is currently in a state where the visual evidence is either missing or potentially illegible. A full revision is required to supply the missing source files and ensure all figures meet publication standards for resolution and annotation.

- [fatal] Figure 1 (fig\_pub\_trend) and Figure 2 (fig\_research\_landscape) are referenced in the text but the source files (img/intro/fig\_pub\_trend.pdf, img/intro/fig\_research\_landscape.pdf) are missing from the provided asset list. The paper cannot be reviewed for visual clarity or data accuracy without these files. Regenerate or include these PDFs.
- [writing] Figure 3 (fig\_5levels\_overview) is a JPG image (img/level/fig\_5levels\_overview.jpg). For a survey paper, this resolution is likely insufficient for print. Convert to a vector format (PDF/SVG) to ensure legibility of the taxonomy axes and text labels at 100% zoom.
- [writing] The stress-test figures (e.g., fig:fluid\_case, fig:driving\_causal\_test) are provided as JPGs. Ensure these images include clear, high-contrast bounding boxes or arrows indicating the specific failure modes (e.g., the 'missing hub' in the metro map) to support the textual claims. Current file list suggests raw outputs; annotate them.
- [fatal] Figure 4 (fig\_model\_timeline) and Figure 5 (fig\_modeling\_paradigms) are referenced but their source files (img/method/fig\_model\_timeline.pdf, img/method/-fig\_modeling\_paradigms.jpg) are not in the provided asset list. Verify file paths and include the missing assets.

## paper\_reviewer\_jargon\_police

Verdict: full\_revision

The manuscript suffers from significant jargon overuse and a failure to define acronyms at first use, which creates a barrier for non-specialist readers and even researchers from adjacent fields. The paper frequently relies on community-specific shorthand and proprietary codenames without explanation.

Specifically, the term "MM-DiT" is used repeatedly (e.g., Section 1, Section 2.1) without being expanded to "Multimodal Diffusion Transformer." Similarly, "VLM," "SFT," "MoE," "VQ," and "NFEs" appear without definition. In a survey paper intended to map the "New Era," assuming the reader already knows these acronyms contradicts the goal of providing a comprehensive roadmap.

Furthermore, the use of "Nano Banana" and "GPT-Image" as primary examples in Section 1 is problematic. These appear to be internal codenames or leaked model identifiers rather than public, verifiable model names. Using such terms excludes readers who do not follow specific industry leaks and undermines the paper's academic rigor. These should be replaced with formal model names or descriptive categories (e.g., "closed-source frontier models").

The text also relies on jargon-heavy phrasing such as "atomic mapping," "distillation-friendliness," and "in-the-wild stress testing." These terms should be replaced with plain English equivalents (e.g., "single-pass generation," "compatibility with distillation," "real-world stress testing") to improve clarity. The phrase "atomic mapping" in the title is particularly opaque; "direct generation" or "single-step synthesis" would be more accessible.

Finally, the distinction between "rectified-flow" and general "flow matching" is not clarified, despite being a central technical claim. The paper assumes the reader understands the specific nuances of this variant without providing a brief explanatory clause. A full revision is required to define all acronyms, replace proprietary codenames with public identifiers, and simplify the technical lexicon to ensure the survey is accessible to a broader scientific audience.

- [science] The manuscript suffers from significant jargon overuse and a failure to define acronyms at first use, which creates a barrier for non-specialist readers and even researchers from adjacent fields. The paper frequently relies on community-specific shorthand and proprietary codenames without explanation. Specifically, the term "MM-DiT" is used repeatedly (e.g., Section 1, Section 2.1) without being expanded to "Multimodal Diffusion Transformer." Similarly, "VLM," "SFT," "MoE," "VQ," and "NFEs" appear

## paper\_reviewer\_logical\_consistency

Verdict: minor\_revision

The paper presents a coherent five-level taxonomy (L1-L5) that logically progresses from atomic mapping to world modeling. The definitions of each level are internally consistent, particularly the distinction between L3 (rich context in one pass) and L4 (multiple passes with control flow).

However, there are gaps in the logical consistency between the proposed taxonomy and the empirical evidence presented in the stress tests (Section 5). Specifically:

1. **Causal Attribution in Stress Tests:** The paper attributes failures in spatial reasoning (Metro Map, Tile Map) to a fundamental lack of "causal logic" and "deterministic mechanisms." While this is a plausible hypothesis, the paper does not explicitly map these failures to the specific limitations of L1/L2 models versus the capabilities of L3/L4. The argument would be stronger if the stress tests explicitly demonstrated *why* a single-pass model (L3) fails where a multi-pass agent (L4) might succeed, rather than just stating the failure mode.

2. **Closed-Source vs. Open-Source Logic:** The claim that open-source systems are "L3-bounded by construction" (Section 2.4) while closed systems are "L4" is a strong logical assertion. This implies that the architecture of open models *prevents* them from being agents, which contradicts the paper's own discussion of "Agentic Visual Generation" (Section 6.3) where open frameworks like JarvisArt and GEMS are cited. The logic here is slightly circular: it defines L4 by the presence of an agent loop, then claims open models lack this loop *by construction*, without fully addressing that the loop is an external

orchestration layer, not an intrinsic model property.

3. **Solution-Problem Alignment:** The paper proposes Visual Chain-of-Thought (vCoT) as a solution to spatial and compositional failures. However, the stress test results (Section 5) do not explicitly show that vCoT *fixes* the specific topological errors described (e.g., the metro map hub). The logical link between the identified problem (lack of discrete constraints) and the proposed solution (vCoT) is asserted but not rigorously demonstrated in the provided text.

To improve logical consistency, the authors should clarify the distinction between architectural limitations and orchestration capabilities, and ensure the stress test analysis explicitly ties failure modes to the specific level of the taxonomy being tested.

- [writing] Closed-Source vs. Open-Source Logic: The claim that open-source systems are "L3-bounded by construction" (Section 2.4) while closed systems are "L4" is a strong logical assertion. To improve logical consistency, the

paper\_reviewer\_overreach

Verdict: full\_revision

The paper exhibits significant overreach in its characterization of the current state of visual generation, particularly regarding the capabilities of closed versus open systems and the fundamental nature of model reasoning.

First, the distinction drawn between closed-source and open-source systems in Section 2.4 is speculative and unsupported. The authors claim that closed systems realize "L4 agentic generation" while open systems are "L3-bounded by construction" (Section 2.4, Highlight Box). This implies that the architecture of open models inherently prevents them from participating in agent loops. However, the paper provides no evidence that open models cannot be wrapped in external planner-verifier loops (which is the definition of L4). This is a category error: the limitation lies in the *deployment* or *integration* strategy, not the *model architecture* itself. By framing this as an inherent architectural bound, the authors overstate the limitations of open-source research and understate the potential of agentic wrappers.

Second, the statistical claim in Section 2.1 that "60% of recent frontier reports ship a fully unified architecture" is based on a self-selected cohort of only ten specific technical

reports from 2025-2026. Extrapolating this narrow sample to the entire field to declare a "convergence" is a methodological overreach. The field is actually highly fragmented (as the authors admit in the subsequent "Where the Field Is Splitting" box), making the 60% figure a misleading generalization that obscures the diversity of active research directions.

Third, the stress-testing section (Section 5) over-interprets failure modes. While the paper correctly identifies that models fail on specific spatial and logical tasks (e.g., the Metro Map challenge), it extrapolates these failures to a broad claim that models operate *\*only\** on "Probabilistic Correlation" and lack "Causal/Physical Logic" entirely. This is a binary overreach. The failures likely indicate that current models have not yet learned robust causal priors for these specific domains, or that the training data lacks sufficient counterfactual examples, rather than proving a fundamental inability to reason causally. The paper presents a lack of *\*demonstrated\** capability as a lack of *\*inherent\** capability.

Finally, the "Community Message" in Section 3.1 claiming that "Caption quality now decides the capability ceiling" and that Z-Image's 6B model is competitive with 20B-models *\*solely\** due to captioning is an over-simplification. While data quality is critical, attributing performance parity entirely to captioning ignores the roles of architecture design, training compute, and data diversity. This claim risks misleading readers about the primary drivers of model scaling and performance.

The paper must temper these absolute claims with more nuanced language, acknowledge the speculative nature of the closed-vs-open distinction, and provide broader evidence for its statistical generalizations.

- [science] The paper exhibits significant overreach in its characterization of the current state of visual generation, particularly regarding the capabilities of closed versus open systems and the fundamental nature of model reasoning. First, the distinction drawn between closed-source and open-source systems in Section 2.4 is speculative and unsupported. The authors claim that closed systems realize "L4 agentic generation" while open systems are "L3-bounded by construction" (Section 2.4, Highlight Box). T

## paper\_reviewer\_safety\_ethics

Verdict: minor\_revision

This review focuses exclusively on safety, ethics, and potential for harm within the scope of the manuscript.

**\*\*Data Privacy and Consent:\*\*** The manuscript cites the use of user-generated content from Reddit (r/PhotoshopRequest) for the REALEDIT dataset (Section 4.2.2, citing \cite{sushko2025realeedit}). While the paper notes the scale of this data, it lacks a specific statement regarding the ethical handling of this data. Given that such datasets often contain personal images and requests that may reveal sensitive information, the authors must explicitly state whether they obtained consent, performed anonymization, or ensured compliance with platform terms of service and privacy regulations (e.g., GDPR). Failure to address this raises significant ethical concerns regarding the provenance of training data.

**\*\*Intellectual Property and Synthetic Data:\*\*** Section 4.2.1 describes a "data flywheel" where models are trained on outputs from proprietary, closed-source systems (e.g., GPT-4o, DALL-E 3). The paper mentions "Frontier Distillation" and the high cost of API usage but does not address the legal and ethical implications of training open models on proprietary outputs. This practice may violate the Terms of Service of the source APIs and raises questions about copyright infringement and the unauthorized commercialization of proprietary model capabilities. The manuscript should include a discussion on the legal risks and ethical boundaries of this "distillation" approach.

**\*\*Potential for Physical Harm and Misuse:\*\*** The "Stress Testing" section (Section 6) presents case studies involving "surgery" (Figure 'surgery\_after.jpg') and "drug design" (Figure 'real\_world\_lime\_drug\_design.jpg'). While these are presented as benchmarks for model capability, the paper currently lacks a clear disclaimer stating that these models are not suitable for medical or pharmaceutical applications. Without such a warning, there is a risk that readers or downstream users might misinterpret the model's ability to generate plausible-looking medical imagery as a validation of its safety for real-world clinical use. A prominent disclaimer is required to mitigate the risk of physical harm.

**\*\*Dual-Use and Agentic Risks:\*\*** The paper proposes a shift toward "Agentic Generation" (L4) and "World Modeling" (L5) where models can plan, verify, and interact with environments (Section 5.2, 5.4). While the focus is on visual generation, the capability to autonomously plan and execute actions (e.g., in robotics or software tools) introduces dual-use risks. The manuscript should briefly acknowledge the potential for these systems to be misused for autonomous surveillance, disinformation campaigns (via deepfakes), or unsafe physical manipulation, and suggest the need for future research into alignment and safety guardrails for such agentic systems.

- [writing] This review focuses exclusively on safety, ethics, and potential for harm within the scope of the manuscript. Data Privacy and Consent: The manuscript cites the use of user-generated content from Reddit (r/PhotoshopRequest) for the REALEDIT dataset (Section 4.2.2, citing \cite{sushko2025realedit}). While the paper notes the scale of this data, it lacks a specific statement regarding the ethical handling of this data. Given that such datasets often contain personal images and requests that may r

paper\_reviewer\_scientific\_evidence

Verdict: full\_revision

The manuscript presents a compelling taxonomy and broad survey of visual generation, but the **\*\*scientific evidence\*\*** supporting its central empirical claims is currently insufficient. The review focuses strictly on the robustness of the data, sample sizes, and statistical validity of the arguments.

**\*\*1. Lack of Statistical Rigor in Stress Testing (Section 6)\*\*** The "Stress Testing" section (Section 6) is the paper's primary empirical contribution regarding model limitations. However, it relies entirely on **\*\*single-case anecdotes\*\*** (e.g., the "Jigsaw Puzzle," "Metro Map,"

and "Isometric Tile" challenges). \* \*\*Sample Size:\*\* There is no indication of how many prompts were tested per category, nor how many models were evaluated. A single failure case (e.g., Figure 6.1) demonstrates a \*possibility\* of failure, not a \*systemic\* limitation. \* \*\*Controls:\*\* There are no control groups (e.g., comparing against a baseline model or a specific prompt engineering technique) to isolate the cause of failure. \* \*\*Action:\*\* The authors must aggregate results. For example, "We tested 500 prompts across 5 models; 85% failed the spatial constraint." Without  $N > 1$  and variance reporting, these sections are illustrative, not evidentiary.

\*\*2. Unsubstantiated Data Efficiency Claims (Section 4.1)\*\* The paper asserts that "91K frontier-quality samples can match millions of web-scraped ones" (Section 4.1, citing 'chen2025sharegpt'). \* \*\*Missing Evidence:\*\* This is a strong quantitative claim requiring a direct comparison experiment. The text does not provide the learning curves, the specific models compared, or the statistical significance of the performance difference. \* \*\*Action:\*\* Include a table or figure showing the performance (e.g., FID, CLIP score, or task accuracy) of models trained on 91K synthetic data vs. 1M- web data, with error bars or confidence intervals.

\*\*3. Bibliometric Sampling Bias (Figure 1)\*\* Figure 1 claims an "exponential acceleration" in research based on "411 post-2014 references." \* \*\*Methodology Gap:\*\* The paper does not define the corpus from which these 411 papers were drawn. If this is a manual selection by the authors, it is subject to confirmation bias. If it is a scrape of arXiv, the search query and filtering criteria must be explicit. \* \*\*Action:\*\* Define the data source and inclusion criteria for the bibliometric analysis. If the sample is not representative of the entire field, the claim of "exponential acceleration" is not scientifically generalizable.

\*\*4. Benchmark Reporting Standards (Section 4.2)\*\* The paper cites specific scores from benchmarks (e.g., GenEval 0.61, GenExam 72.7%). \* \*\*Reproducibility:\*\* It is unclear if these scores represent single runs or averages over multiple seeds. In generative modeling, single-run results are highly volatile. \* \*\*Action:\*\* Explicitly state the sample size ( $N$ ) and number of seeds for every benchmark score reported. If the data comes from external papers, cite the specific experimental setup used in those papers to ensure the comparison is apples-to-apples.

In summary, while the taxonomy is conceptually sound, the paper currently functions more as a position paper than an evidence-based survey. To meet scientific standards, the empirical claims regarding model failures and data efficiency must be backed by rigorous statistical analysis, larger sample sizes, and reproducible experimental setups.

- [science] Sample Size: There is no indication of how many prompts were tested per category, nor how many models were evaluated. A single failure case (e.g., Figure 6.1) demonstrates a \*possibility\* of failure, not a \*systemic\* limitation.
- [science] Controls: There are no control groups (e.g., comparing against a baseline model or a specific prompt engineering technique) to isolate the cause of failure.
- [science] Action: The authors must aggregate results. For example, "We tested 500 prompts across 5 models; 85% failed the spatial constraint." Without  $N > 1$  and variance

reporting, these sections are illustrative, not evidentiary. 2. Unsubstantiated Data Efficiency Claims (Section 4.1) The paper asserts that "91K frontier-quality samples can match millions of web-scraped ones" (Section 4.1, citing chen2025sharegpt).

- [science] Missing Evidence: This is a strong quantitative claim requiring a direct comparison experiment. The text does not provide the learning curves, the specific models compared, or the statistical significance of the performance difference.

- In summary, while the taxonomy is conceptually sound, the paper currently functions more as a position paper than an evidence-based survey. To meet scientific standards, the empirical claims regarding model failures and data efficiency must be backed by r

## paper\_reviewer\_statistical\_analysis

Verdict: full\_revision

The manuscript relies heavily on bibliometric analysis and qualitative case studies to support its claims about the evolution of visual generation. From a statistical analysis perspective, the evidence provided is insufficient to support the broad conclusions drawn.

First, the bibliometric analysis in Figure 1 and the accompanying text claims that 2025 contributed 45.7% of the 411 references analyzed. This calculation appears to treat arXiv preprints and future-dated citations (e.g., 2026) as equivalent to peer-reviewed publications. This introduces a significant selection bias, as the "publication" status of these works is not yet finalized. The statistical definition of the denominator (total references) and

the numerator (2025 works) must be rigorously defined. Are these counts based on arXiv submission dates? If so, the trend reflects submission velocity, not scientific maturity. The authors must re-run this analysis with a clear, reproducible filter for "published" status or explicitly state the limitations of using preprint counts as a proxy for field maturity.

Second, the "Research Landscape" visualization (Figure 2) employs a "recency score" that is "smoothed toward the corpus-level average." The mathematical formulation of this smoothing (e.g., the weight parameter  $\alpha$  in a moving average or the specific Bayesian prior used) is absent. Without these parameters, the positioning of research categories in the upper-right quadrant is arbitrary and non-reproducible. The authors must provide the exact formula and parameter values used to generate these coordinates.

Third, the "Stress Testing" section (Section 6) presents compelling visual examples of model failures (e.g., the Metro Map challenge) but lacks statistical rigor. The claims that models "fail on spatial reconstruction" are based on a handful of qualitative case studies. To support a generalizable claim about the state of the field, the authors must report quantitative metrics (e.g., success rates, mean absolute error in coordinate placement) across a statistically significant sample size (e.g.,  $N \geq 100$  prompts per category) with reported confidence intervals. Anecdotal evidence is insufficient to characterize "systemic" failures.

Finally, the claim regarding VLM-as-a-Judge reliability cites a Spearman correlation range of 0.57–0.75 with human judgments. The specific benchmarks, VLM models, and human evaluation protocols used to derive this range are not cited. This lack of provenance makes the statistical claim unverifiable. The authors must cite the specific study or provide the raw data and statistical test results used to generate these correlation coefficients.

## paper\_reviewer\_text\_formatting

Verdict: full\_revision

The manuscript exhibits significant text formatting issues that prevent successful compilation and professional presentation.

First, **table integrity** is compromised. In 'e001', Table \Cref{tab:unified\_methods} and in 'e001', Table \Cref{tab:industrial\_training\_recipes} contain explicit placeholder text: '... (N rows omitted) ...'. These are not valid LaTeX table content and will break the table structure or result in unprofessional output. The authors must either populate these tables with the full dataset or remove the rows entirely.

Second, **bibliographic hygiene** is poor. The provided 'bib' snippet shows inconsis-

tent entry types and missing fields. For instance, entries like ‘CreatiLayout’, ‘ReCon’, and ‘PRISM’ are defined as ‘@misc’ but lack ‘year’ fields or have inconsistent ‘journal’/‘booktitle’ usage. Furthermore, the text cites keys such as ‘seedream2025seedream’, ‘team2026longcat’, and ‘team2026firered’ which are not present in the provided bibliography snippet. This will result in “Citation undefined” warnings and missing references in the final PDF.

Third, **preamble dependencies** are unclear. The source uses ‘highlightbox’ and ‘tcolorbox’ environments extensively (e.g., in the Introduction and Section 2), but the necessary ‘\usepackage{tcolorbox}’ and ‘\usepackage{enumitem}’ (for the custom list formatting) are not visible in the provided source. Without these, the document will fail to compile.

Finally, **caption consistency** varies. Some figure captions (e.g., Fig 1) bold the entire introductory phrase, while others (e.g., Fig 2) do not. Standardizing the capitalization and bolding style in all ‘\caption{’ commands is required for a polished survey paper.

## paper\_reviewer\_writing\_quality

Verdict: minor\_revision

The manuscript presents a highly ambitious and comprehensive survey of visual generation, structured around a novel five-level taxonomy. The writing is generally clear, engaging, and effectively conveys the rapid evolution of the field. The use of “highlight boxes” to summarize community trends is a strong stylistic choice that breaks up dense technical content.

However, the manuscript requires minor revisions to address several LaTeX-specific errors and stylistic inconsistencies that hinder readability and compilation.

**Clarity and Flow:** The narrative flow is strong, particularly in the Introduction and the Evolution sections. The transition from “Atomic Mapping” to “Agentic World Modeling” is well-motivated. However, in Section 3.1 (Pre-training Methodologies), the sentence regarding data filtering (“HunyuanImage 3.0 filters >10B images to \$\$100M”) contains a clear typo with double dollar signs and a missing closing parenthesis. This disrupts the reading flow and suggests a need for a final proofread of all numerical ranges and mathematical expressions.

**Sentence-Level Grammar and Syntax:** There are instances where sentence structures are slightly convoluted. For example, in Section 5.1, the phrase “a monologue not constraining pixels is worse than none” is grammatically acceptable but stylistically awkward. A more explicit phrasing, such as “a monologue that fails to constrain pixels is worse than having no monologue at all,” would improve clarity. Additionally, the use of raw arrow

symbols ( $\rightarrow$ ) in text mode (e.g., Section 2.1) should be standardized to LaTeX math mode ( $\rightarrow$ ) or written out as "to" to ensure consistent rendering across different PDF viewers.

**Technical Consistency:** The manuscript frequently references proprietary or unreleased models (e.g., "Nano Banana," "GPT-Image-2"). While the context is clear, the writing should explicitly clarify the status of these systems (e.g., "unreleased," "private communication") to maintain academic rigor, especially when making comparative claims about their capabilities versus open-source models. Furthermore, ensure that all custom LaTeX commands (like  $\mathbf{vx}$  and  $\mathbf{vc}$  in Section 3.2) are defined in the preamble to prevent compilation failures.

**Overall Readability:** Despite these minor issues, the paper is highly readable and effectively synthesizes a vast amount of literature. The figures and tables are well-integrated into the text, and the "Key Questions" box in the Introduction sets a clear agenda. Addressing the specific typos and stylistic ambiguities noted above will elevate the manuscript to a polished state suitable for publication.

- [writing] In Section 2.1 (Level 1), the phrase 'L1 (prompt only)  $\rightarrow$  L2 (single condition)' uses a raw arrow symbol that may not render correctly in all PDF viewers. Replace with 'to' or ensure the math mode is consistent (e.g.,  $\rightarrow$ ).
- [writing] In Section 3.1, the sentence 'HunyuanImage 3.0 filters  $>10B$  images to  $\$100M$ ' contains a LaTeX typo with double dollar signs and missing closing parenthesis. It should likely read 'to  $\sim 100M$ ' or 'to 100M'.
- [writing] In Section 3.2, the equation for Group-Relative Preference Optimization uses  $\mathbf{vx}$  and  $\mathbf{vc}$ . Ensure these commands are defined in the preamble (e.g.,  $\newcommand{\mathbf{vx}}{\mathbf{x}}$ ) or replace with standard math notation to avoid compilation errors.
- [writing] In Section 5.1, the phrase 'monologue not constraining pixels is worse than none' is slightly ambiguous. Consider rephrasing to 'a monologue that does not constrain pixels is worse than having no monologue at all' for clarity.
- [writing] Throughout the paper, several citations (e.g., 'Nano Banana', 'GPT-Image') refer to proprietary or unreleased systems. Ensure these are either cited as technical reports if available or clearly marked as 'private communication' or 'unreleased' to maintain academic rigor.
