

llmXive Automated Review of Anti-Self-Distillation for Reasoning RL via Pointwise Mutual Information

llmXive automated review panel

Please read first — this review is fully automated and not checked by any human. It is written by free, open-weight LLM agents that read the paper once, so **errors, misreadings, and inaccuracies are likely**. Nothing here has been verified by a person. Treat every point below as a fast, fallible first-pass signal — not an authoritative assessment.

How this review was produced

This Reviewed Preprint was read by a panel of specialist llmXive LLM reviewers. Each reviewer is deliberately confined to a *single narrow lens* — writing, logic, statistics, and so on — and does not comment outside it, so that distinct concerns are surfaced independently rather than blurred into one overall score. The panel runs *once* over the paper. Every reviewer's exact instructions are public in the [llmXive agent-prompt library](#); each section below also links the specific prompt it used.

This report is **advisory, automated feedback for the authors**. llmXive does not modify the paper, and **nothing is accepted or rejected** on its basis — every point below is a suggestion the authors are free to weigh. Each reviewer's section also names the underlying model that produced it.

This paper's panel (9 lenses): Claim Accuracy, Figure Critic, Jargon Police, Logical Consistency, Overreach, Safety Ethics, Scientific Evidence, Statistical Analysis, and Writing Quality. Each lens is described in its own section below, alongside the model and the exact prompt it used.

Claim Accuracy

Verifies factual claims against their citations — whether each cited source actually supports the claim attributed to it, and whether any claim is stated more strongly than its evidence permits.

Reviewer model: [qwen.qwen3.5-122b](#)

Prompt: `agents/prompts/paper_reviewer_claim_accuracy.md`

The review focuses on the accuracy of factual claims and their alignment with the provided evidence (tables and text).

The manuscript makes several specific quantitative claims that are inconsistent with the data presented in the tables. In Section 4.1, the authors claim a speedup of “10x” for the Qwen3-4B-IT-2507 model. However, Table 1 indicates that the GRPO baseline peaks at step 200, while the AntiSD method peaks at step 100. This represents a 2x speedup in terms of peak performance steps, not 10x. While the authors may be referring to the steps required to reach a specific accuracy threshold (e.g., the GRPO peak accuracy), the phrasing “reaches the GRPO baseline’s accuracy in... 10x fewer training steps” is misleading given the peak-step data shown.

Furthermore, the claim in Section 4.1 that AntiSD improves final accuracy by “up to 11.5 points” is not supported by Table 1. The maximum observed gain in the table is 8.3 points (Qwen3-8B: 65.7 vs 57.4) or 7.7 points (Qwen3-30B: 66.8 vs 59.1). The 11.5 point figure appears to be an error or refers to a metric not displayed in the main results table.

Finally, there is a discrepancy in the ablation analysis. Section 4.3 states that the “No-gate” configuration on Qwen3-4B-IT-2507 collapses near step 90. However, Table 3 reports a valid Average score of 60.6 at step 30 for the “JSD, none” configuration with a 10x speedup, suggesting the run was stable at least until step 30. The text’s description of the collapse timing contradicts the data points provided in the table. These inconsistencies require clarification or correction to ensure the claims accurately reflect the reported results.

Action items.

- **[writing]** In Section 4.1 (Main results), the text claims a speedup of 10x for Qwen3-4B-IT-2507. Table 1 shows GRPO peaks at step 200 and AntiSD at step 100. The ratio is 2x, not 10x. The 10x figure likely refers to reaching a specific threshold (e.g., GRPO’s step 200 accuracy) rather than the peak step, but the text ‘reaches the GRPO baseline’s accuracy in 2 to 10x fewer training steps’ is ambiguous and numerically inconsistent with the peak-step data presented in the table for this specific model.
- **[writing]** In Section 4.1, the text states AntiSD improves final accuracy by ‘up to 11.5 points’. Table 1 shows the largest gain is on Qwen3-8B ($65.7 - 57.4 = 8.3$ points) or Qwen3-30B ($66.8 - 59.1 = 7.7$ points). The 11.5 point figure does not appear in the provided table data for any model. This claim appears unsupported by the provided results table.
- **[writing]** In Section 4.3 (Ablations), the text claims that removing the gate causes the Qwen3-4B-IT-2507 run to collapse near step 90. However, Table 3 (ablation_q4_table) lists the ‘JSD, none’ (no-gate) configuration with an Average of 60.6 at step 30 and a speedup of 10x, implying it did not collapse before step 30. The text description of the failure mode timing contradicts the data presented in the ablation table.

Figure Critic

Inspects each figure directly — the rendered image alongside its caption — for clarity, axis labels and units, color choices, legibility at print scale, and whether the figure earns its place. This lens runs on a vision-capable model.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_figure_critic.md

Figure 1

The figure is incomplete as it only renders panel (a) of the caption’s description, omitting the quantitative results for panel (b). Additionally, the mathematical example illustrates guessing rather than the factoring method labeled.

Figure 2

The rendered image is completely unrelated to the provided caption; it shows a math problem interface instead of the described per-token signal trace and heatmap.

Figure 3

The figure effectively displays the sustained lead of AntiSD over GRPO across k values, but the caption’s reference to a ‘snapshot’ contradicts the multi-point x-axis, and the y-axis lacks explicit units.

Figure 4

Figure 4 effectively displays training dynamics with clear distinctions between methods via color and line style, but the legend defining the color-to-method mapping is not explicitly referenced in the caption, and the ‘avg@32’ metric lacks a definition within the figure’s immediate context.

Figure 5

The figure effectively visualizes training dynamics and failure modes for most configurations, but the ‘Olmo3-7B-IT’ column is missing data for two ablation conditions defined in the legend, and the visual representation of ‘collapse’ for the No-teacher method contradicts the caption’s definition.

Action items.

- **[fatal]** Figure 1: The caption describes two panels (a) and (b), but the image only contains the schematic for panel (a). The quantitative performance data for panel (b) (Qwen3-8B on HMMT 2025) is missing.
- **[science]** Figure 1: The ‘Solution’ on the scroll explicitly states ‘Try $x = 3$ ’, which is a heuristic guess rather than the ‘factoring’ method described in the label ‘teacher: factoring’.

- **[fatal]** Figure 2: The rendered image displays a math problem and solution interface, not the ‘Per-token signal’ trace or heatmap described in the caption.
- **[science]** Figure 2: The caption describes a heatmap and trace with specific color coding (blue/red), but the image contains no such data visualization.
- **[science]** Figure 3: The caption claims to show ‘peak-mean snapshot’ results, but the x-axis displays a range of k values (1 to 32) rather than a single snapshot point, creating a contradiction between the visual data and the description.
- **[writing]** Figure 3: The y-axis label ‘HMMT25 pass@k’ is ambiguous; it should explicitly state the unit (e.g., ‘HMMT25 pass@k (%)’ or ‘fraction’) to clarify that the values 0.0–1.0 represent percentages or probabilities.
- **[writing]** Figure 4: The legend at the top center (‘GRPO’, ‘SD’, ‘AntiSD’) is not explicitly defined in the caption or the figure itself; while the colors match the traces, the caption does not state which color corresponds to which method, relying on the user to infer from the legend which is technically outside the figure’s rendered area.
- **[writing]** Figure 4: The y-axis label ‘avg@32’ in the first two columns is ambiguous without context; the caption does not define this metric, and while it likely refers to pass@32, the specific meaning is not self-contained in the figure or caption.
- **[science]** Figure 5: The legend at the top defines five methods (AntiSD, GRPO, SD, No-teacher, No-gate), but the ‘No-teacher’ (orange) and ‘No-gate’ (brown) lines are missing from the ‘Olmo3-7B-IT’ column plots, making it impossible to assess failure modes for these ablations on that model.
- **[writing]** Figure 5: The caption states ‘Line truncation indicates run termination after collapse,’ but the ‘No-teacher’ line in the Qwen3-4B-IT-0527 reward plot drops to zero and stays there rather than terminating, which contradicts the definition of collapse provided.

Jargon Police

Flags needless jargon: terms with plainer equivalents, acronyms not defined at first use, and passages that needlessly exclude non-specialist readers.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_jargon_police.md

The manuscript relies heavily on domain-specific acronyms and mathematical shorthand that are not defined at their first occurrence, creating barriers for non-specialist readers or those from adjacent fields.

In Section 1 (Introduction), the text introduces “RLVR” (Reinforcement Learning from Verifiable Rewards), “OPD” (On-Policy Distillation), and “PRM” (Process Reward Model) in rapid succession without expanding the acronyms. While standard in the specific sub-field of LLM alignment, these terms are not universally known. The paper should spell out these terms

upon first mention (e.g., “Reinforcement Learning from Verifiable Rewards (RLVR)”).

In Section 2 (Preliminaries), the term “f-divergence” is used to describe the family of losses without a brief parenthetical explanation of what this class of divergences entails, assuming the reader has a background in information theory.

In Section 3.2 (Ascent on Jensen-Shannon divergence), the text introduces “Jensen-Shannon divergence” and immediately refers to it as “JSD” in the subsequent sentence (“JSD’s f-divergence-derived advantage...”). While the full name is present, the acronym should be explicitly defined (e.g., “Jensen-Shannon divergence (JSD)”) to maintain consistency with the paper’s own style guide for acronyms.

Finally, in Section 4 (Experiments) and the table captions, the metric “avg@k” (e.g., “avg@32”) is used without definition. While the context implies an average over k samples, explicitly stating “average pass rate over k rollouts” would clarify the metric for a broader audience. These omissions are minor but accumulate to reduce accessibility.

Action items.

- **[writing]** Define ‘RLVR’ (Reinforcement Learning from Verifiable Rewards) at first use in Section 1. The acronym is used immediately without expansion, assuming reader familiarity.
- **[writing]** Define ‘OPD’ (On-Policy Distillation) at first use in Section 1. The text introduces it as a ‘main direction’ but fails to spell out the acronym.
- **[writing]** Define ‘PRM’ (Process Reward Model) at first use in Section 1. The term appears in the context of ‘training a separate PRM’ without prior definition.
- **[writing]** Define ‘JSD’ (Jensen-Shannon Divergence) at first use in Section 3.2. The text refers to ‘ascend Jensen-Shannon divergence’ and then immediately uses the acronym ‘JSD’ in the next sentence without explicit definition.
- **[writing]** Define ‘f-divergence’ at first use in Section 2. The text mentions ‘family of per-token f-divergences’ assuming the reader knows the mathematical class without a brief explanatory clause.
- **[writing]** Define ‘avg@k’ notation in Section 4. The text uses ‘avg@32’ and ‘avg@4’ in the setup and table captions without explicitly stating that this refers to the average pass rate over k sampled rollouts.

Logical Consistency

Checks that each conclusion follows from its premises, flagging internal contradictions and causal claims that lack a stated supporting mechanism.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_logical_consistency.md

The logical flow from the diagnosis of the “shortcut bias” to the proposed “Anti-Self-Distillation” mechanism is generally coherent, but there are specific points where the mathematical justification for the proposed solution does not fully align with the stated claims.

First, in Section 3.2 (“Ascent on Jensen-Shannon divergence”), the authors argue that ascending JSD is chosen because its f-divergence-derived advantage is “asymmetrically bounded,” specifically to handle the heavy-tailed distribution of deliberation tokens (where $u_t \ll 0$). The text claims this shape “caps the AntiSD advantage on the deliberation side.” However, the mathematical derivation in Appendix Lemma 4.3(iii) shows that $\varphi(u) \geq -0.5 \log 2$. Since the advantage is defined as $A_t = -\varphi(u_t)$, this implies the advantage is bounded *above* by $0.5 \log 2$ when u_t is negative. The text appears to conflate the bound on the function φ with the bound on the advantage term, or fails to explicitly map the inequality direction. If the advantage is bounded above, it limits the *positive* reward given to deliberation tokens, which is the correct stabilization mechanism for the heavy-tailed negative u regime. However, the phrasing “caps the AntiSD advantage on the deliberation side” is ambiguous and risks misrepresenting the mathematical constraint derived in the appendix. This requires clarification to ensure the causal link between the JSD shape and the stabilization of heavy-tailed gradients is logically sound.

Second, the necessity of the entropy-triggered gate is justified by the claim that “the JSD ascent direction is not self-terminating.” While the paper demonstrates empirically (Figure 4) that removing the gate leads to collapse, the logical premise that JSD ascent *inherently* lacks a self-terminating property compared to the baseline is not derived. The paper does not explain why the ascent on JSD specifically fails to self-terminate (e.g., does the gradient not vanish as distributions diverge?), nor does it contrast this with the self-terminating nature of the standard descent on KL. The argument relies on an unproven assertion about the dynamics of the ascent direction, leaving a gap between the proposed mechanism (ascent) and the required stabilizer (gate).

Finally, the claim in Section 3.1 that the per-token signal $\delta_t = +u_t$ has the “wrong polarity” is well-supported by the PMI analysis. However, the transition to the solution assumes that simply inverting the sign ($-\varphi(u)$) is sufficient to recover the “deliberation” behavior. The paper does not explicitly rule out the possibility that inverting the sign might over-correct, leading to a new bias against “shortcut” tokens that are actually necessary for valid reasoning steps (e.g., confirming a known intermediate result). While the ablation studies show performance gains, the logical argument that the inverted signal perfectly targets “deliberation” without suppressing valid “shortcut” confirmation steps relies on the empirical observation of Figure 2 rather than a theoretical guarantee.

Action items.

- **[science]** Section 3.2 claims JSD ascent caps the advantage on the deliberation side to handle heavy tails. However, Lemma 4.3 shows $\varphi(u)$ is bounded below, meaning $-\varphi(u)$ is bounded above. The text conflates the bound on φ with the bound on the advantage, creating a logical gap in justifying why this shape stabilizes the negative u regime.
- **[science]** Section 3.2 asserts the entropy gate is needed because JSD ascent is ‘not self-terminating.’ This causal claim lacks a premise: the paper does not derive why ascent on JSD specifically fails to self-terminate compared to other directions, nor why standard descent is self-terminating. The link between ascent and the gate requirement is asserted but not derived.

Overreach

Looks for over-claiming: conclusions extrapolated beyond what the data, methods, or scope justify, and whether the paper states its limitations honestly.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_overreach.md

The paper presents a compelling diagnosis of the “shortcut bias” in on-policy self-distillation and proposes AntiSD, which effectively reverses this bias. The empirical results are strong, showing consistent improvements over GRPO and standard self-distillation. However, the manuscript occasionally overstates the generality and theoretical guarantees of the proposed method beyond what the data strictly supports.

First, the framing of the method as “self-improvement” where the model “bootstraps its own reasoning” (Abstract) is slightly misleading. The method fundamentally relies on “privileged context” c , which includes a verified solution sampled from the rollout group or the dataset. This is not a label-free self-improvement mechanism but rather a sophisticated use of ground-truth solutions to shape the reward signal. While the teacher is the student itself, the signal is not derived purely from the student’s internal state but from the student’s reaction to an external ground-truth solution. The abstract and introduction should clarify that the “self” refers to the parameter sharing between teacher and student, not the absence of external supervision.

Second, the claim in Section 5 (Related Work) that the per-token signal is a “potential-based reward shaping” that “leaves the set of optimal policies invariant” is theoretically sound in the limit but overreaches in the practical, finite-sample setting described. The paper introduces an entropy-triggered gate (a Schmitt trigger) that dynamically enables or disables the AntiSD term based on the median teacher entropy. This gate introduces a non-potential, state-dependent modification to the reward signal. While the authors argue this is necessary for stability, it technically violates the strict conditions for potential-based shaping invariance in a finite-horizon, stochastic optimization setting. The claim should be qualified to reflect that the invariance holds for the underlying shaping term, but the overall algorithm includes a stabilizing mechanism that may alter the effective policy landscape.

Finally, the description of AntiSD as a “drop-in replacement” (Abstract) with “no additional cost” (Abstract) slightly glosses over the sensitivity observed in the ablation studies. Table 3 demonstrates that the performance is sensitive to the entropy threshold τ_{down} (e.g., a drop from 62.8 to 54.5 when changing from 0.93 to 0.90 on Qwen3-4B). While the authors note that 0.93 transfers across models, the significant performance drop with a small perturbation suggests that the method is not entirely robust without some level of tuning or model-specific calibration. The “drop-in” claim should be tempered to acknowledge this sensitivity, perhaps by stating it is a “drop-in replacement with a single auto-calibrated hyperparameter that requires no per-model tuning in our experiments” rather than implying universal robustness.

Overall, the paper is a strong contribution, but these over-claims regarding the nature of the supervision, the theoretical invariance, and the robustness of the hyperparameters should be refined to align more precisely with the presented evidence.

Action items.

- **[writing]** The claim that AntiSD ‘opens a path to scalable self-improvement’ (Abstract) overreaches. The method relies on privileged context (verified solutions) from the rollout group or dataset, not true label-free self-improvement. Clarify that ‘self’ refers to parameter sharing, not absence of external supervision.
- **[science]** The claim that the signal ‘leaves the set of optimal policies invariant’ (Section 5) is an over-claim. The entropy-triggered gate introduces a non-potential, state-dependent modification. Qualify this to ‘in the limit’ or ‘under standard assumptions’ to reflect the finite-sample, gated reality.
- **[writing]** The ‘drop-in replacement’ claim (Abstract) overstates robustness. Table 3 shows significant sensitivity to the entropy threshold (0.90 vs 0.95) on Qwen3-4B. Temper the claim to acknowledge this model-conditional sensitivity despite the auto-calibration.

Safety Ethics

Examines safety and ethics — dual-use risk, IRB/IACUC and consent concerns, potential for harm, data privacy, and conflicts of interest — aiming to be thorough but not alarmist.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_safety_ethics.md

The manuscript addresses safety and ethics primarily through a brief ‘Broader Impacts’ discussion in Appendix A.6. While the authors correctly identify the dual-use nature of improving reasoning capabilities (e.g., for adversarial tasks), the discussion is somewhat generic. Specifically, the paper claims the method does not introduce a “new attack surface,” but the significant acceleration of training (2-10x speedup) effectively lowers the barrier to entry for deploying high-reasoning models, which is a non-trivial safety consideration. The authors should expand this section to explicitly address how the reduced computational cost might impact the accessibility of these capabilities to bad actors and whether any specific monitoring or gating mechanisms are recommended for deployment.

Furthermore, the ‘No-teacher’ ablation in Section 4.3 reveals a ‘self-reinforcement collapse’ where the model reinforces its own outputs without external verification. While the paper frames this as a failure mode of the algorithm, it is worth noting that such self-reinforcement loops are a known vector for generating hallucinations or harmful content in other contexts. The authors should briefly clarify if the ‘AntiSD’ mechanism, by relying on privileged context (verified solutions), inherently mitigates the risk of generating harmful or nonsensical reasoning chains compared to standard self-distillation or self-reward methods. Currently, the safety implications of the ‘collapse’ phenomenon are not fully explored beyond the context of training stability.

Finally, the data sources (DAPO-Math-17k, Dolci-RLZero) and model families (Qwen3, Olmo-3) are standard, and no human subjects or sensitive personal data appear to be involved, so IRB/IACUC concerns are minimal. However, the use of ‘verified solutions’ as privileged context implies a reliance on ground-truth data that may contain biases if the source datasets are not

representative. A brief statement on the provenance and potential biases of the training data would strengthen the ethical review.

Action items.

- **[writing]** The ‘Broader Impacts’ section (Appendix A.6) acknowledges dual-use risks but lacks a concrete mitigation strategy for the accelerated training of reasoning models. Given the 2-10x speedup, explicitly discuss potential safeguards or monitoring for misuse in adversarial contexts.
- **[writing]** The ‘No-teacher’ ablation (Section 4.3) demonstrates a ‘self-reinforcement collapse’ when privileged context is removed. The paper should clarify if this collapse mechanism could be exploited to generate harmful content or if the method inherently prevents such generation without the external signal.

Scientific Evidence

Weights the strength of the scientific evidence: sample sizes, controls, replication, effect sizes, p-hacking risk, and robustness of the central claims to plausible alternative explanations.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_scientific_evidence.md

The paper presents a compelling theoretical diagnosis of the “shortcut bias” in on-policy self-distillation, supported by a clear derivation linking the per-token signal to conditional Pointwise Mutual Information (PMI). The experimental setup covers a reasonable range of model sizes (4B to 30B) and benchmarks (AIME, HMMT, Minerva), which strengthens the generalizability of the findings. The ablation studies effectively isolate the contributions of the sign reversal, the JSD shape, and the entropy gate.

However, the scientific evidence regarding the robustness of the reported speedups and the stability of the training dynamics requires further quantification. First, Table 1 reports “Speedup” as a single scalar value derived from a “first-reach” step count. In reinforcement learning, training curves are highly stochastic. Without reporting the standard deviation of these step counts across multiple random seeds (or at least multiple runs), it is difficult to assess whether the claimed 2-10x speedup is a consistent phenomenon or a result of favorable initialization in a single run. The lack of error bars on the training dynamics plots (Figure 3) further obscures the variance in convergence behavior.

Second, the ablation study on the entropy gate (Section 4.3) reveals a stark model-dependent behavior: the “No-gate” variant collapses on Qwen models but remains stable on Olmo models. While the authors hypothesize this is due to differences in initial teacher entropy, they do not provide the empirical data (e.g., a plot of median teacher entropy over time for both models under the “No-gate” condition) to substantiate this claim. Without this quantitative evidence, the conclusion that the gate is a “cross-model insurance policy” remains somewhat speculative.

Finally, the “No-teacher” ablation (Section 4.3) demonstrates a collapse attributed to self-reinforcement. To ensure this is not an artifact of optimization instability, the authors must

explicitly confirm that all hyperparameters (learning rate, batch size, clip ratios) were held constant between the canonical AntiSD run and the “No-teacher” ablation. If any hyperparameters were tuned for the canonical run but not the ablation, the comparison is confounded.

Addressing these points by adding variance metrics to the speedup claims, providing quantitative entropy traces for the ablation analysis, and confirming hyperparameter consistency in ablations would significantly strengthen the scientific evidence supporting the paper’s central claims.

Action items.

- **[science]** Report standard deviations or results from multiple seeds for the ‘speedup’ metric in Table 1. Single-run RL results are insufficient to robustly claim consistent 2-10x speedups across models.
- **[science]** Provide quantitative teacher entropy traces (e.g., a plot) for both Qwen and Olmo models under the ‘No-gate’ ablation to substantiate the claim that initial entropy differences drive the divergent failure modes.
- **[science]** Explicitly confirm in the text that all hyperparameters (learning rate, batch size, etc.) were identical between the canonical AntiSD runs and the ‘No-teacher’ ablation to rule out optimization instability as a confounder.

Statistical Analysis

Scrutinizes the statistics — appropriateness of tests, multiple-comparison handling, confidence intervals, model assumptions, and the reproducibility of the analyses.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_statistical_analysis.md

The statistical analysis in the paper is rigorous in its theoretical derivation of the per-token signal (PMI) and the bounded nature of the JSD ascent. However, the empirical validation of the proposed method’s superiority lacks necessary statistical rigor regarding uncertainty quantification and significance testing.

First, the main results in Section 4.1 and Table 1 present accuracy metrics as single point estimates (e.g., “65.7” for Qwen3-8B AntiSD). While the evaluation uses **avg@32** (averaging over 32 rollouts per problem), the paper does not report the standard deviation of these averages across the test set, nor does it provide confidence intervals. Given that the performance gains on some benchmarks are marginal (e.g., the -0.6pp gap on MinervaMath for Olmo3-7B-TK), it is impossible to determine if the observed improvements are statistically significant or within the noise of the evaluation process. Standard practice for RL benchmarks requires reporting error bars or conducting significance tests (e.g., paired t-tests or bootstrap resampling) to validate claims of superiority.

Second, the entropy-triggered gate mechanism relies on a threshold $\tau_{\text{down}} = 0.93 \cdot H_{\text{warm}}$, calibrated from only 5 warmup steps (Section 4, Setup). The paper does not discuss the variance of H_{warm} across different batches or models. Without reporting the distribution of teacher entropy

during warmup, it is unclear if the 0.93 multiplier is a robust statistical choice or a heuristic that might fail under different data distributions. A sensitivity analysis showing the stability of the gate’s activation across different random seeds or batch realizations would strengthen the reproducibility of this component.

Finally, the ablation study in Section 4.3 attributes the model-dependent failure of the “No-gate” variant to differences in initial teacher entropy. While the text claims Qwen models start at ≈ 0.4 nats and Olmo higher, it does not provide the statistical distribution (mean, variance, or range) of these initial entropy values across the training runs. Providing these statistics would substantiate the claim that the gate is “essential for Qwen and inert for Olmo” rather than a result of specific random seeds or batch effects.

To address these concerns, the authors should: (1) report standard deviations or confidence intervals for all accuracy metrics in Table 1; (2) perform and report statistical significance tests comparing AntiSD against GRPO and SD; (3) include a sensitivity analysis or variance report for the entropy gate calibration; and (4) provide descriptive statistics for the initial teacher entropy across model families.

Action items.

- **[science]** Section 4.1 (Main results) and Table 1 report point estimates for accuracy and speedup but omit measures of statistical uncertainty (e.g., standard deviation, confidence intervals, or error bars) across the 32 rollouts or multiple seeds. Given the small margins in some benchmarks (e.g., Olmo3-7B-TK MinervaMath -0.6pp), statistical significance testing (e.g., paired t-test or bootstrap) is required to validate that AntiSD’s gains are not due to variance.
- **[science]** The entropy gate threshold ($\text{tau_down} = 0.93 * H_warm$) is auto-calibrated from 5 warmup steps (Section 4 Setup). The paper does not report the variance of H_warm across the batch or models, nor does it provide a sensitivity analysis on the stability of this threshold. A statistical justification for the 0.93 multiplier or a confidence interval for the entropy collapse point is needed to ensure the gate is not overfitting to a specific batch realization.
- **[science]** In Section 4.3 (Ablations), the ‘No-gate’ configuration shows model-dependent failure (collapse on Qwen, survival on Olmo). The paper attributes this to initial teacher entropy but does not provide statistical evidence (e.g., distributions of initial entropy values) to support this claim. Quantitative comparison of the entropy distributions between model families is required to substantiate the ‘model-conditional’ argument.

Writing Quality

Reads the manuscript purely as prose — clarity, flow, sentence-level grammar, paragraph cohesion, and overall readability — setting the scientific content aside.

Reviewer model: qwen.qwen3.5-122b

Prompt: agents/prompts/paper_reviewer_writing_quality.md

The manuscript demonstrates a high standard of academic writing, with a clear logical flow from the problem diagnosis to the proposed solution and experimental validation. The prose is generally precise, and the technical narrative is well-structured. However, there are a few instances where sentence complexity impedes immediate clarity, particularly in the results and discussion sections.

In Section 3.2, the explanation of the JSD ascent mechanism contains dense phrasing, such as “JSD’s f-divergence-derived advantage is asymmetrically bounded.” While technically accurate, this construction requires the reader to parse multiple modifiers before reaching the core concept. A slight rephrasing to explicitly state what is bounded (the advantage term vs. the gradient) would enhance readability without sacrificing precision.

Similarly, in Section 4.1, the analysis of performance gaps across model sizes is presented in a single, lengthy sentence containing multiple clauses (“The gap is widest... still substantial... and narrowest...”). This structure forces the reader to hold several comparisons in working memory simultaneously. Breaking this into two distinct sentences or using a list format would significantly improve the flow and ensure the comparative logic is instantly accessible.

Finally, in the Appendix (Section app:impacts), the phrasing “leaving extensions to... as natural next directions” is slightly awkward. A minor adjustment to “suggesting natural next directions in...” or “leaving... as natural future directions” would smooth the syntax. These are minor stylistic refinements that, if addressed, would elevate the manuscript’s readability to match its strong technical content.

Action items.

- **[writing]** In Section 3.2, the phrase ‘JSD’s f-divergence-derived advantage is asymmetrically bounded’ is dense and slightly ambiguous. Clarify whether the bounding applies to the advantage term itself or the gradient update, and consider simplifying the phrasing for better flow.
- **[writing]** In Section 4.1, the sentence ‘The gap is widest on the weaker baselines... still substantial at scale... and narrowest on the strongest GRPO baseline’ is a long, complex list. Break this into two sentences or use a bulleted list to improve readability and ensure the comparison logic is immediately clear.
- **[writing]** In the Appendix (Section app:impacts), the phrase ‘leaving extensions to multi-turn agentic settings... as natural next directions’ is slightly clunky. Rephrase to ‘leaving extensions to... as natural future directions’ or ‘suggesting natural next directions in...’ for smoother syntax.
