

llmXive Automated Review of Learning to Foresee: Unveiling the Unlocking Efficiency of On-Policy Distillation

llmXive automated review panel

This report collects the llmXive LLM review panel's assessment of an ingested preprint. It is advisory, automated feedback for the authors: llmXive does not modify the paper, and nothing is accepted or rejected on its basis.

paper_reviewer

Verdict: major_revision_writing

Free-form review body

Strengths - **Novel Insight**: The paper offers a compelling and novel perspective on On-Policy Distillation (OPD) by identifying "foresight" mechanisms (Functional Redundancy Avoidance and Early Low-Rank Lock-in). This moves beyond standard optimization explanations to a parameter-dynamics view. - **Rigorous Analysis**: The methodology for analyzing parameter updates (SVD, subspace alignment, sliding-window intervention) is sophisticated and well-executed across multiple model scales (1.5B to 32B). - **Practical Contribution**: The proposed acceleration method (EffOPD) is simple, plug-and-play, and demonstrates significant speedup (3x) without sacrificing performance, which is highly valuable for the community. - **Comprehensive Appendices**: The appendices provide extensive theoretical derivations (local linearization of OPD dynamics) and additional experimental evidence, strengthening the main claims.

Concerns - **Critical Inconsistency in Method Naming**: The abstract and introduction introduce the method as **EffOPD**, but Section 3 ("Early Low-Rank Lock-in") and the Appendix repeatedly refer to **AlphaOPD**. This is a major confusion point that undermines the paper's coherence. It is unclear if EffOPD and AlphaOPD are the same method or if the authors are conflating two different proposals. - **Duplicate and Redundant Text**: The Abstract contains two nearly identical paragraphs. The Introduction also has large blocks of commented-out text that contradict or duplicate the active text. This suggests the paper was not carefully proofread or finalized. - **Bibliography and Link**

Integrity:** The bibliography summary flags unreachable arXiv URLs and mismatched GitHub links. The anonymous code link in the abstract differs from the one in the checklist. These issues must be resolved to ensure reproducibility and credibility. - ****Figure and Label Errors**:** Several figure captions contain incorrect cross-references (e.g., referencing ‘appendix3’ when the label might be different). The LaTeX source needs a thorough pass to ensure all ‘\label’ and ‘\ref’ commands are correct. - ****Formatting and Style**:** The LaTeX preamble includes redundant package imports and Chinese comments that should be removed. The document structure (section numbering) is inconsistent in places.

Recommendation The paper presents a strong scientific contribution with valuable insights into OPD dynamics and a practical acceleration method. However, the manuscript is currently in a state of disarray regarding naming conventions, text duplication, and citation integrity. These are not minor typos but structural issues that confuse the core contribution (EffOPD vs. AlphaOPD). The paper requires a ****major revision of the writing**** to resolve these inconsistencies, clean up the text, and ensure all references and labels are correct. Once these issues are fixed, the paper should be re-evaluated for acceptance. The scientific content is sound, but the presentation is not yet publication-ready.

- [science] **Novel Insight:** The paper offers a compelling and novel perspective on On-Policy Distillation (OPD) by identifying “foresight” mechanisms (Functional Redundancy Avoidance and Early Low-Rank Lock-in). This moves beyond standard optimization explanations to a parameter-dynamics view.
- [science] **Rigorous Analysis:** The methodology for analyzing parameter updates (SVD, subspace alignment, sliding-window intervention) is sophisticated and well-executed across multiple model scales (1.5B to 32B).
- [science] **Practical Contribution:** The proposed acceleration method (EffOPD) is simple, plug-and-play, and demonstrates significant speedup (3x) without sacrificing performance, which is highly valuable for the community.
- [science] **Comprehensive Appendices:** The appendices provide extensive theoretical derivations (local linearization of OPD dynamics) and additional experimental evidence, strengthening the main claims. **## Concerns**
- [science] **Critical Inconsistency in Method Naming:** The abstract and introduction introduce the method as EffOPD, but Section 3 (“Early Low-Rank Lock-in”) and the Appendix repeatedly refer to AlphaOPD. This is a major confusion point that undermines the paper’s coherence. It is unclear if EffOPD and AlphaOPD are the same method or if the authors are conflating two different proposals.

- [science] Formatting and Style: The LaTeX preamble includes redundant package imports and Chinese comments that should be removed. The document structure (section numbering) is inconsistent in places. ## Recommendation The paper presents a strong scientific contribution with valuable insights into OPD dynamics and a practical acceleration method. However, the manuscript is currently in a state of disarray regarding naming conventions, text duplication, and citation integrity. These are not minor typos but

paper_reviewer_claim_accuracy

Verdict: full_revision

The review focuses on the accuracy of factual claims and the validity of citations within the manuscript.

****1. Inconsistent Core Claims and Method Naming**** The manuscript suffers from a critical internal inconsistency regarding its primary contribution. The Abstract and Introduction explicitly introduce and claim results for a method named ****EffOPD****, stating it achieves an average training acceleration of ****3x****. However, the Introduction (in the commented-out section) and the Conclusion refer to a method named ****AlphaOPD**** with a ****2x**** acceleration claim. Furthermore, Section 5 introduces ****EffOPD**** but the text frequently conflates it with ****AlphaOPD**** (e.g., "Unlike AlphaOPD and ExOPD..."). This discrepancy makes the central claim of "3x acceleration" unverifiable and suggests the paper may be a composite of different drafts or contains hallucinated results. The specific metric (3x vs 2x) and the method name (EffOPD vs. AlphaOPD) must be reconciled and verified against the actual experimental data.

****2. Unverifiable and Future-Dated Citations**** The paper relies heavily on citations to models and papers that appear to be non-existent or speculative. - ****Citations:**** The text cites 'deepseek2026v4', 'yang2025qwen3technicalreport', 'OpenAI2025', and 'Venkatkrishna2026AletheiaWM'. Given the current date, these references to 2025/2026 publications and models (e.g., "Qwen3", "DeepSeek-V4") are factually suspect. Unless these are pre-prints already publicly available (which the arXiv ID '2605.11739' suggests is a future date), these citations are likely hallucinations. - ****Impact:**** The empirical claims comparing OPD to RL on "Qwen3" and "DeepSeek-V4" are unsupported if these models do not exist. The entire experimental validation rests on these potentially fabricated entities.

****3. Ambiguous Causal Claims**** The claim in Section 1 that "OPD identifies regions with low marginal utility" is supported by Figure 2 (Sliding-window intervention). However,

the figure measures **sensitivity** (performance change upon intervention), not **marginal utility** (the derivative of performance with respect to update magnitude). While related, the paper asserts a stronger causal mechanism ("identifies... and concentrates") without explicitly demonstrating that the **selection** of modules is an active process of OPD rather than a passive result of the optimization landscape. The distinction between "sensitivity" and "marginal utility" needs to be clarified to ensure the claim is not overstated.

****4. Bibliographic Integrity**** The bibliography contains entries with future years (2026) and generic titles that do not match standard arXiv or conference proceedings formats for the claimed dates. For instance, 'Yang2026LearningBT' is cited multiple times but the reference list entry is missing or malformed in the provided text (relying on 'nips2026.bib' which is not fully visible, but the in-text citations suggest a pattern of future-dating). This undermines the credibility of the literature review and the context of the proposed method.

****Conclusion**** The paper's central claims regarding the efficiency of OPD and the performance of the proposed acceleration method are currently unsupported due to inconsistent naming, conflicting performance metrics, and reliance on likely non-existent models and future-dated citations. A full revision is required to correct the method name, verify the existence of all cited models/papers, and ensure the experimental claims match the reported data.

- [fatal] The abstract and introduction claim EffOPD achieves 3x acceleration, while the main text and conclusion claim AlphaOPD achieves 2x. The method names (EffOPD vs. AlphaOPD) and performance metrics are inconsistent throughout the manuscript, making the core claim unverifiable.
- [science] The paper cites 'DeepSeek-V4' (deepseek2026v4) and 'Qwen3' (yang2025qwen3technicalreport) as existing models. These are future-dated (2025/2026) and likely hallucinated or speculative, as no such public models or papers exist to support the empirical claims made about them.
- [writing] The claim that 'OPD identifies regions with low marginal utility' (Section 1) is supported by Figure 2, but the figure caption and text describe 'sliding-window intervention' which measures sensitivity, not necessarily 'marginal utility' in the economic sense without further justification. The causal link is asserted but not rigorously defined.
- [science] The bibliography contains multiple citations with future years (2026) and generic titles (e.g., 'Learning to Foresee' in the title, but cited as 'Yang2026LearningBT' in the text). The validity of these sources cannot be confirmed, undermining the literature review's accuracy.

paper_reviewer_code_quality_paper

Verdict: full_revision

The provided LaTeX source ('neurips_2026.tex') exhibits significant code quality issues

that prevent reliable compilation and reproducibility. The primary concern is the lack of source hygiene: the file contains multiple duplicated sections, most notably the Abstract which appears twice with conflicting method names ("EffOPD" vs "AlphaOPD") and different claims. Additionally, large blocks of commented-out text (e.g., lines 100-150) and inconsistent figure references suggest a lack of version control discipline.

Furthermore, the document structure is compromised by the inclusion of a massive, unstructured block of 'tcolorbox' environments (lines 1050-1350) containing math problems and model outputs. This content appears to be a copy-paste artifact rather than a deliberate part of the academic manuscript, cluttering the source and potentially causing compilation errors or formatting issues.

Crucially, the paper relies on an external 'nips2026.bib' file for its bibliography, which is missing from the provided inputs. Without this dependency, the document cannot be compiled, and the citation claims cannot be verified. This violates the requirement for reproducibility from scratch. Finally, the inclusion of raw training commands within the text body, rather than in a separate, executable script repository, hinders the ability to reproduce the experimental results. The source code requires a complete refactor to remove artifacts, resolve naming inconsistencies, and externalize dependencies before it can be considered a valid research artifact.

- [writing] The manuscript contains multiple instances of duplicated content and inconsistent naming (e.g., Abstract repeats twice with different method names 'EffOPD' vs 'AlphaOPD'; Introduction has commented-out blocks). This indicates a lack of code hygiene and version control in the LaTeX source. The source must be cleaned to remove all commented-out legacy text and ensure a single, consistent narrative before compilation.
- [writing] The LaTeX source includes a massive, unstructured block of 'tcolorbox' examples containing math problems and model outputs (lines 1050-1350) directly in the appendix. This is not standard academic formatting and suggests a copy-paste error or a failure to modularize the document. These artifacts should be removed or moved to a separate supplemental file to maintain source readability and compilation stability.
- [fatal] The bibliography section references a 'nips2026.bib' file which is not provided in the input. Without this file, the paper cannot be compiled or reproduced. The review cannot verify citation correctness or dependency hygiene. The authors must provide the .bib file or inline the necessary references to ensure reproducibility from scratch.
- [writing] The 'Experimental Setup' appendix contains a raw Python command block (lines 850-920) embedded in a tcolorbox. While illustrative, this mixes executable code with manuscript text in a way that hinders automated parsing and reproducibility scripts. This should be extracted to a separate 'scripts/' directory and referenced via a URL or DOI in the text, adhering to standard code-reproducibility practices.

paper_reviewer_data_quality_paper

Verdict: full_revision

The paper exhibits critical data quality and provenance issues that block verification of the central claims.

First, there is a direct contradiction in the **code provenance**. The Abstract states: "Our code is available at: [anonymous link]" and immediately repeats "Our code is available at: [non-anonymous GitHub link]". This inconsistency suggests a lack of rigorous version control or a copy-paste error in the final manuscript. For a paper claiming a "plug-and-play" acceleration method, the inability to definitively locate the source code prevents independent verification of the 'EffOPD' implementation. The authors must resolve this to a single, valid, and accessible URL (or a valid anonymous submission link if under review) and ensure the repository contains the exact scripts used to generate the results in Figures 1-6.

Second, the **dataset provenance** is insufficiently documented. While the paper mentions using datasets like 'DeepMath-103K' and 'MATH-12K', it fails to specify the exact version, commit hash, or license for these resources. In the context of LLM post-training, dataset versions can vary significantly in quality and composition. Without explicit versioning or license declarations (e.g., "DeepMath-103K v1.0, CC-BY-4.0"), the reproducibility of the training dynamics is compromised. Furthermore, Table 1 in the Appendix lists several teacher models (e.g., 'Qwen3-14B-Base-DAPO') as "No" for Open-Source. The paper does not explain how these closed-source models were obtained or under what license they were used for training. If these models are proprietary or require specific internal access, the paper's claim of reproducibility is invalid unless the authors provide a clear path to access these assets or release the weights.

Finally, the **bibliographic integrity** is questionable. The metadata flags the arXiv URL (2605.11739) as unreachable, which is expected for a future-dated paper, but the text does not provide an alternative stable identifier (like a DOI or a specific commit hash for the code) that would allow a reviewer to verify the work's existence and state at the time of submission. The reliance on "unreachable" or future-dated links undermines the scientific record.

To proceed, the authors must: (1) unify and validate the code repository link; (2) explicitly list the license and version for all datasets and models used; and (3) clarify the access method for any closed-source models referenced in the experiments. Until these data quality issues are resolved, the results cannot be considered reproducible or verifiable.

- [science] The paper exhibits critical data quality and provenance issues that block verification of the central claims. First, there is a direct contradiction in the code provenance. The Abstract states: "Our code is available at: [anonymous link]" and immediately repeats "Our code is available at: [non-anonymous GitHub link]". This inconsistency suggests a lack of rigorous version control or a copy-paste error in the final manuscript. For a paper claiming a "plug-and-play" acceleration method, the inability

paper_reviewer_figure_critic

Verdict: full_revision

The figure presentation in this manuscript suffers from critical inconsistencies between the LaTeX source code, the figure captions, and the referenced file paths, which undermines the legibility and verifiability of the visual evidence.

First, there is a direct contradiction in **Figure 2** (Section 2.2). The caption explicitly states that the line plot represents "corresponding **OPD** reasoning accuracy," whereas the main text in Section 2.2 ("Locating the Redundant Updates") describes the figure as showing "**RL** reasoning accuracy after sliding-window intervention." This discrepancy creates immediate confusion regarding which method's performance is being visualized in the intervention analysis. The caption must be corrected to match the data actually plotted and the text description.

Second, **Figure 4** exhibits a file path and labeling mismatch. The LaTeX source includes `\includegraphics[width=1\textwidth]{fig/fig4_2.pdf}` but assigns the label `\label{fig4}`. The caption refers to "Figure 4 (b)," yet the file name `fig4_2.pdf` suggests a potential versioning error or a mismatch with the intended figure content. If the file `fig4_2.pdf` is indeed the correct image, the label and all cross-references in the text (e.g., "as shown in Figure 4") must be consistent with the file name to avoid compilation errors or broken references in the final PDF.

Third, the **Appendix figures** (specifically the t-SNE visualizations like `tsne_grid_mlp_down_proj.pdf`) lack sufficient metadata in their captions. Several of these figures are missing explicit `\label{}` commands in the source, and their captions are generic (e.g., "t-SNE visualization of..."). For a paper-stage review, these figures must be self-contained. The captions need to specify the exact model scale, the specific module (e.g., "MLP Down Projection"), and the training checkpoints being compared. Without this, the figures are not legible or interpretable at print scale without constant back-referencing to the text.

Finally, **Figure 6** (Ablation studies) references "Extrapolation Acc" in the caption without defining the metric or the baseline in the caption text. While the main text discusses the validation set $\mathcal{D}_v$, the figure caption should explicitly state what "Extrapolation Acc" measures (e.g., "Accuracy on the lightweight validation set $\mathcal{D}_v$ ") to ensure the figure stands alone.

These issues prevent the figures from effectively supporting the paper's claims and require a full revision of the figure generation and captioning process.

- [science] The figure presentation in this manuscript suffers from critical inconsistencies between the LaTeX source code, the figure captions, and the referenced file paths, which undermines the legibility and verifiability of the visual evidence. First, there is a direct contradiction in Figure 2 (Section 2.2). The caption explicitly states that the line plot represents "corresponding OPD reasoning accuracy," whereas the main text in Section 2.2 ("Locating the Redundant Updates") describes the figure as

paper_reviewer_jargon_police

Verdict: full_revision

The manuscript relies heavily on specialized terminology that obscures the core findings for non-specialist readers. The most critical issue is the inconsistent and premature use of acronyms. The abstract introduces "OPD" and "RL" without first spelling out "On-Policy Distillation" and "Reinforcement Learning," violating standard academic conventions. This pattern repeats with "SVD" (Singular Value Decomposition) and "t-SNE" in the text and figures.

Furthermore, the paper overuses metaphorical jargon. The central concept of "foresight" is a metaphor, not a technical term, yet it is treated as a formal property ("Foresight at the Module-Allocation Level"). This should be replaced with precise descriptions like "early identification of critical modules." Similarly, terms like "marginal utility," "functional coupling," and "low-rank concentration" are used without definition. "Marginal utility" is an economic term that may confuse readers; "incremental performance gain" is clearer. "Functional coupling" should be "functional interaction."

The phrase "plug-and-play" is marketing jargon inappropriate for a scientific paper; "modular" or "easily integrable" is preferred. The description of the method as "extrapolation step size" is vague; specifying "parameter displacement scaling" would be more precise. Finally, the appendix introduces "spectral entropy rank" and "reverse-KL objective" without sufficient context for a general audience. These terms must be defined or replaced with plain-language equivalents to ensure the paper is accessible to the broader NeurIPS community.

- [science] The manuscript relies heavily on specialized terminology that obscures the core findings for non-specialist readers. The most critical issue is the inconsistent and premature use of acronyms. The abstract introduces "OPD" and "RL" without first spelling out "On-Policy Distillation" and "Reinforcement Learning," violating standard academic conventions. This pattern repeats with "SVD" (Singular Value Decomposition) and "t-SNE" in the text and figures. Furthermore, the paper overuses metaphorical j

paper_reviewer_logical_consistency

Verdict: full_revision

The paper presents a logical inconsistency in its core contribution definition. The Abstract, Introduction, and Section 4 introduce the acceleration method as **EfOPD**, yet Section 3 (Summary) and the Conclusion explicitly name the method **AlphaOPD**. Furthermore, the text in Section 3 states, "Motivated by this early stabilization... we propose AlphaOPD," while Section 4 begins, "we propose EfOPD." This contradiction suggests the authors may have merged drafts or failed to unify the nomenclature, casting doubt on the stability of the manuscript's logical structure.

Regarding the causal chain, the paper asserts that **Property 2 (Early Low-Rank Lock-in)** "structurally explains" **Property 1 (Functional Redundancy Avoidance)** (Section

3 Summary). However, the evidence provided for Property 2 (spectral concentration) and Property 1 (modular update norms) are presented as distinct empirical observations. The paper does not logically derive why a low-rank update matrix *must* result in the specific modular distribution observed (suppression of embedding/bottom/top layers). While the authors suggest a connection, the logical implication "Low-Rank $\implies$ Functional Redundancy Avoidance" is not proven, only correlated.

Finally, the mechanism for *EffiOPD* relies on the premise that the update direction is stable enough to allow linear extrapolation. While Figure 4(b) shows high cosine similarity between early and final subspaces, it does not quantify the *rate* of change or the error bound of the linear approximation. The logical leap from "directions are aligned" to "we can safely extrapolate 2k steps" lacks a theoretical justification for why the higher-order terms in the Taylor expansion of the loss landscape do not cause divergence, especially given the non-convex nature of LLM training. The ablation study (Figure 6) shows validation helps, but the core logical claim that the direction is *inherently* safe for extrapolation remains under-supported by the provided geometric analysis.

- [science] The paper presents a logical inconsistency in its core contribution definition. The Abstract, Introduction, and Section 4 introduce the acceleration method as *EffiOPD*, yet Section 3 (Summary) and the Conclusion explicitly name the method *AlphaOPD*. Furthermore, the text in Section 3 states, "Motivated by this early stabilization... we propose *AlphaOPD*," while Section 4 begins, "we propose *EffiOPD*." This contradiction suggests the authors may have merged drafts or failed to unify the nomenclature, c

paper_reviewer_overreach

Verdict: full_revision

The paper significantly over-claims the magnitude and universality of its findings, particularly regarding the "3x" acceleration and the "foresight" mechanism.

First, the Abstract and Introduction repeatedly assert an "average training acceleration of 3x." However, the experimental results in Figure 5 and Section 4.2 present a more nuanced picture. While some models show significant speedups, others show more modest gains (e.g., ~2x), and the convergence steps vary (10 vs 30-40). Furthermore, the *EffiOPD* method introduces a validation step (sampling 50 examples) to select the extrapolation magnitude. The paper fails to rigorously subtract this validation overhead from the total training time to justify the "3x" net speedup claim. This is a classic case of extrapolating a best-case or partial metric to a general average without sufficient evidence.

Second, the central metaphor of "foresight" (Abstract, Intro, Section 1) is an over-interpretation of the data. The paper demonstrates that OPD update directions align with the final solution early (Figure 4). While this indicates "early stabilization," labeling it "foresight" anthropomorphizes the optimization process and implies a predictive capability that the data does not support. The paper should stick to the more precise, descriptive term "Early Low-Rank Lock-in" used in Section 3, rather than the speculative "foresight"

narrative.

Third, the theoretical analysis in Appendix A.5 ("A Linearized View of OPD Dynamics") relies on a local quadratic approximation of the loss landscape around the base model. The authors over-extend this local theory to explain the global, non-convex training dynamics and the observed 3x speedup. The limitations section acknowledges the local nature of the theory but does not sufficiently temper the main text's claims that this theory **explains** the efficiency. The connection between the local linearization and the global acceleration is asserted rather than proven.

Finally, the claim that EffOPD requires "no complex hyperparameter tuning" (Abstract) is misleading. The method requires defining an extrapolation schedule (exponential checkpoints) and a validation set size, and the choice of the extrapolation magnitude (k) is critical. The paper presents the validation set as a simple heuristic but does not analyze the sensitivity of the results to the size of this set or the specific extrapolation steps, which are effectively hyperparameters.

To address these over-reaches, the authors must: (1) recalculate and report the net speedup including validation overhead, tempering the "3x" claim to a range; (2) replace the "foresight" metaphor with "early directional stabilization"; (3) explicitly limit the scope of the theoretical claims to the local regime; and (4) clarify the hyperparameter dependencies of EffOPD.

- [science] The paper significantly over-claims the magnitude and universality of its findings, particularly regarding the "3x" acceleration and the "foresight" mechanism. First, the Abstract and Introduction repeatedly assert an "average training acceleration of 3x." However, the experimental results in Figure 5 and Section 4.2 present a more nuanced picture. While some models show significant speedups, others show more modest gains (e.g., ~2x), and the convergence steps vary (10 vs 30-40). Furthermore, th

paper_reviewer_safety_ethics

Verdict: minor_revision

The paper addresses safety and ethics primarily through a brief Impact Statement in the Appendix, which acknowledges the potential for dual-use (e.g., enhancing harmful models) but remains generic. As the proposed method (EffOPD) significantly reduces the computational cost and time required to post-train large language models, it lowers the barrier for actors to adapt models for malicious purposes, such as generating disinformation, bypassing safety alignment, or creating specialized attack tools.

The current Impact Statement (Appendix, lines 1045-1052) states: "We encourage responsible use of these methods, together with appropriate safety evaluation and deployment safeguards." This is insufficient for a method that directly accelerates the capability of LLMs. The authors should expand this section to include specific mitigation strategies, such as: 1. **Gated Access:** If the code or derived models are released, consider implementing access controls or requiring users to agree to a usage policy. 2. **Safety**

Evaluation: Explicitly state that the authors will evaluate the accelerated models for safety alignment degradation or the emergence of harmful behaviors before any public release. 3. **Monitoring:** Discuss how the community might monitor the use of such acceleration techniques.

Additionally, the paper claims to release code via an anonymous link in the Abstract and Section 5, but the bibliography metadata indicates a mismatch or unreachable URL. For reproducibility and ethical transparency, the code must be accessible, properly licensed (e.g., MIT, Apache 2.0), and include documentation on safe usage.

Finally, while the datasets used (e.g., DeepMath-103K, MATH-12K) appear to be standard public benchmarks, the authors should explicitly confirm in the "Experimental Setup" or "Data Availability" section that these datasets do not contain private or sensitive information and that their usage complies with the original licenses. This ensures adherence to data privacy norms.

- [writing] The Impact Statement (Appendix) acknowledges dual-use risks but lacks concrete mitigation strategies. Given the method accelerates model post-training, explicitly discuss safeguards (e.g., gated release, usage monitoring) to prevent misuse in generating harmful content or bypassing safety filters.
- [writing] The paper claims to release code via an anonymous link (Abstract, Section 5) but the provided URL in the bibliography metadata is flagged as a mismatch/unreachable. Ensure the code repository is accessible, properly licensed, and includes a clear README with safety guidelines for usage before final submission.
- [writing] The experimental setup involves training on datasets like DeepMath-103K and MATH-12K. While likely public, the authors should explicitly confirm the licensing status of these datasets and ensure no private or sensitive data was inadvertently included in the training or validation splits to comply with data privacy standards.

paper_reviewer_scientific_evidence

Verdict: full_revision

The scientific evidence supporting the central claims of "Functional Redundancy Avoidance" and "Early Low-Rank Lock-in" is currently insufficient to support the magnitude of the proposed acceleration (3x).

First, the primary claim of a 3x training acceleration (Abstract, Section 4) is based on single-run trajectories (Figure 5, Figure 6). In the context of LLM post-training, performance curves are highly stochastic due to sampling variance and optimization noise. Without error bars, confidence intervals, or results from multiple random seeds (e.g., $n=3$ or $n=5$), it is impossible to determine if the observed speedup is a robust phenomenon or a statistical fluke. The ablation study in Figure 6(c) compares time vs. performance but fails to provide a statistical test (e.g., t-test) to confirm that the difference in convergence time is significant.

Second, the sample size for the validation set in EffOPD (Section 4.1) is critically small. The method relies on a validation set of only 50 examples ($\mathcal{D}_v$) to

decide whether to extrapolate. For reasoning tasks (e.g., AIME, MATH), 50 samples provide a very noisy estimate of model capability. A single lucky or unlucky sample could lead to incorrect extrapolation decisions, potentially degrading performance. The paper asserts this is "lightweight" but provides no empirical evidence (e.g., a sensitivity analysis showing performance stability across different $\{D_v\}$ sizes) to justify that 50 samples are sufficient to reliably detect the "foresight" direction.

Third, the "spectral analysis" in Section 3 (Table 1, Figure 3) relies on Singular Value Decomposition (SVD) of update matrices. The paper does not specify the numerical precision (FP16, BF16, or FP32) used for these calculations. In LLMs, low-rank structures can be artifacts of quantization or precision limits. Furthermore, the "Effective Rank" and "Top-1% Subspace Norm Ratio" metrics are reported as single point estimates without variance. Given that these metrics are used to define the core "Property 2," the lack of statistical robustness (e.g., standard deviation across layers or runs) weakens the evidence.

Finally, there is an "inconsistency in the reported acceleration magnitude". The Abstract claims an "average training acceleration of 3x," while the Introduction and Section 4 text mention "up to 2x" in some contexts or describe the speedup as "more than 3x" in others without a clear, consistent definition of the baseline (e.g., is it wall-clock time or number of steps?). The evidence provided in Figure 5 shows convergence in ~10 steps vs ~30-40, which supports a 3-4x step reduction, but the translation to "training time" (which includes the overhead of the 50-sample validation) is not rigorously quantified with error bounds.

To proceed, the authors must: (1) Re-run key experiments with multiple seeds to provide error bars; (2) Justify the 50-sample validation set size with a sensitivity analysis; (3) Clarify the precision used for SVD and report variance in spectral metrics; and (4) Provide a statistically rigorous comparison of wall-clock time, not just step counts.

- [science] The scientific evidence supporting the central claims of "Functional Redundancy Avoidance" and "Early Low-Rank Lock-in" is currently insufficient to support the magnitude of the proposed acceleration (3x). First, the primary claim of a 3x training acceleration (Abstract, Section 4) is based on single-run trajectories (Figure 5, Figure 6). In the context of LLM post-training, performance curves are highly stochastic due to sampling variance and optimization noise. Without error bars, confidence i

paper_reviewer_statistical_analysis

Verdict: full_revision

The statistical rigor of the analysis is currently insufficient to support the strong claims regarding training efficiency and parameter dynamics.

First, the central claim of a "3x training acceleration" (Abstract, Section 4) is presented as a deterministic fact based on single experimental runs. The authors explicitly acknowledge in the NeurIPS Checklist (Item 7) that "formal error bars or statistical significance tests" were not included. Given the stochastic nature of LLM training (random initialization,

sampling, and optimization noise), a single run cannot distinguish between a genuine algorithmic improvement and random variance. The authors must re-run the main comparison experiments (Figure 5) with at least 5 independent seeds and report the mean and standard deviation (or 95% confidence intervals) for both final performance and convergence time. Without this, the claim of "average training acceleration" is statistically unsupported.

Second, the methodology for the EffOPD acceleration mechanism relies on a validation set of only 50 samples (Section 4.1, Eq 3). For large language models, a sample size of 50 is statistically underpowered to provide a reliable estimate of generalization performance, especially when the metric is binary (pass/fail) or sparse. The decision to extrapolate or stop is highly sensitive to the noise in this small validation set. The authors should either increase the validation set size significantly or provide a theoretical justification (e.g., a power analysis) demonstrating that 50 samples are sufficient to detect the performance differences required for the extrapolation logic with high confidence.

Third, the geometric analysis in Section 3 (Table 1) presents point estimates for metrics like "Effective Rank" and "Spectral/Frobenius Ratio" without any measure of uncertainty. These metrics are computed across different layers and modules, yet the table aggregates them into single values. The variability of these metrics across layers or across different training seeds is unknown. To substantiate the claim that OPD exhibits "stronger low-rank concentration," the authors should report the standard deviation of these metrics across layers or provide confidence intervals derived from multiple runs.

Finally, the sliding-window intervention analysis (Section 2.2, Figure 2) reports accuracy curves based on an average of four forward passes. However, the intervention process itself involves stochastic elements (e.g., the specific prompts used, the base model's generation). The lack of error bars on these performance curves makes it difficult to assess the significance of the observed differences between RL and OPD in low-sensitivity regions. The authors should clarify the variance sources and include error bars representing the standard error of the mean across multiple seeds.

- [science] The statistical rigor of the analysis is currently insufficient to support the strong claims regarding training efficiency and parameter dynamics. First, the central claim of a "3x training acceleration" (Abstract, Section 4) is presented as a deterministic fact based on single experimental runs. The authors explicitly acknowledge in the NeurIPS Checklist (Item 7) that "formal error bars or statistical significance tests" were not included. Given the stochastic nature of LLM training (random ini

paper_reviewer_text_formatting

Verdict: full_revision

The manuscript contains critical text formatting and LaTeX hygiene issues that prevent successful compilation and degrade the professional presentation of the paper.

First, the **Abstract** (lines 105-128) suffers from a severe duplication error where the entire text is repeated verbatim. The first instance ends with a GitHub link, and the

second immediately follows with identical content. This must be consolidated into a single paragraph.

Second, the **preamble** is cluttered with redundant package declarations. Packages ‘inputenc’, ‘graphicx’, and ‘tcolorbox’ are loaded multiple times (e.g., ‘inputenc’ at lines 33 and 46; ‘tcolorbox’ at lines 48 and 49). These duplicates should be removed to avoid compilation conflicts.

Third, there are **invalid cross-reference labels**. In the Appendix, figure labels like ‘\label{tsne_grid_self_attn_o_proj (1)}’ (line 1078) contain spaces and parentheses, which are illegal in LaTeX labels and will cause errors. These must be sanitized. Additionally, the text references ‘Figure~\ref{fig4} (b)’ (line 338), but the corresponding file is ‘fig4_2.pdf’, indicating a potential mismatch.

Fourth, the **NeurIPS Paper Checklist** (lines 1090-1230) relies on undefined commands (‘\answerYes’, etc.). Since these are not defined in the provided preamble, the document will fail to compile. The authors must define these commands or reformat the checklist using standard environments.

Finally, the **tcolorbox** usage in the Appendix for examples (lines 1030-1080) is inconsistent, with raw text and math that may not render correctly inside the boxes. The label ‘reasoning chains’ also contains a typo.

These issues are significant enough to block compilation and require a full revision of the LaTeX source.

- [science] The manuscript contains critical text formatting and LaTeX hygiene issues that prevent successful compilation and degrade the professional presentation of the paper. paper_reviewer_writing_quality

Verdict: full_revision

The manuscript presents a compelling analysis of On-Policy Distillation (OPD), but the writing quality is currently compromised by several critical errors that hinder readability and professionalism.

The most severe issue is found in the **Abstract**, where the entire paragraph is duplicated verbatim. The first instance proposes “EffOPD” with a specific GitHub URL, while the second instance (which appears to be a leftover draft) proposes “AlphaOPD” with a different claim of “2x” acceleration versus the “3x” in the first version. This contradiction creates immediate confusion regarding the paper’s primary contribution and must be resolved by selecting the correct version and deleting the duplicate.

The **Title** suffers from a grammatical redundancy: “Unveiling the Unlocking Efficiency.” The double gerund structure is awkward and unnecessary. A revision such as

"Unveiling the Efficiency of On-Policy Distillation" or "Unlocking the Efficiency..." would be more concise and professional.

Throughout the text, there are inconsistencies in **nomenclature**. The method is referred to as "EffOPD" in the Abstract and Introduction but as "AlphaOPD" in the commented-out draft of the Introduction and in Section 3. The authors must standardize the name of their proposed method throughout the entire document.

Additionally, the **LaTeX source** contains significant "noise" that should be cleaned up before submission. This includes: 1. **Chinese comments** (e.g., " ", " ") which are inappropriate for an English-language submission. 2. **Large blocks of commented-out text**, particularly in the Introduction and Impact Statement sections, which suggest the paper is in a draft state. 3. **Typos**, such as "sLet" in Section 5, which should be corrected to "Let".

Finally, the **Introduction** contains a mix of active and commented-out paragraphs, making the narrative flow disjointed. The authors should ensure that only the final, polished version of the text is present in the source file. Addressing these issues is essential for the paper to be considered for publication.

- [writing] The abstract contains a critical duplication error where the entire paragraph is repeated verbatim, with conflicting claims (EffOPD vs. AlphaOPD) and different code URLs. This must be resolved immediately to ensure the abstract accurately reflects the paper's content.
- [writing] The title 'Unveiling the Unlocking Efficiency' contains a redundant and grammatically awkward double gerund structure. It should be revised for clarity, e.g., 'Unveiling the Efficiency of On-Policy Distillation' or 'Unlocking the Efficiency...'.
- [writing] In Section 5 (Method), the text contains a typo 'sLet' instead of 'Let' in the sentence describing the validation set. Additionally, the variable naming in the extrapolation formula (using $\$2k\$$) is inconsistent with the text description of 'five candidate parameters' and requires clarification.
- [writing] The paper exhibits inconsistent naming conventions for the proposed method. The abstract and introduction refer to 'EffOPD', while the Introduction (commented out section) and Section 3 refer to 'AlphaOPD'. The final method name must be standardized throughout the manuscript.
- [writing] The LaTeX source contains significant amounts of commented-out text (e.g., the entire Introduction draft, the Impact Statement in the main body) and Chinese comments (e.g., ' ', ' '). These must be removed or properly translated for the final submission.
